# Technical features

## 1. GENERAL

The choice of a bearing depends on many factors that need to be examined in order to obtain the most successful results at the lowest cost.

In most cases the selection should be made when the overall design of the machine has been decided. Dimensional limits are then known, also the speeds and loads. At this stage the choice can be made from the many types of bearings offered from the standard ranges. The notes given in this section will generally permit one to select the most suitable bearing for each application.

As for all other types of bearing, the results obtained with needle bearing products depend to a large extent on the design and method of assembly, loading, and alignment between inner and outer rings.

Bearing alignment depends first of all on the geometry of the parts involved and secondly on the deflection of the shaft under load. The shaft diameter should therefore be sufficient to prevent large deflections. This is easier to achieve using needle bearings because they occupy a small radial area.

## 2. BEARING TYPE SELECTION

Bearing type selection is made after the general design concept of the mechanism has been established and the application requirements carefully evaluated.

The ability of a bearing to support radial or axial loads, tolerate misalignments, be suitable for high speeds or loads are the main criteria for guiding the selection in the correct way. To navigate the families of bearings in this catalogue an initial assessment can be made on the basis of the table below. Further details are specified in the relevant chapters.

	Radial needle roller cage	Caged needle bushes	Full complement needle bushes	Caged needle bearings	Full complement needle bearings	Needle rollers	Thrust bearings	Combined bearings <sup>1)</sup>
Radial load	High	Moderate	High	High	Very high	Very high	None	High

## 3. CALCULATIONS FOR RADIAL AND THRUST BEARINGS

The details following enable one to evaluate lifetime of radial bearings and thrust bearings and also combined bearings which comprise a radial and a thrust component. These are calculated separately without transforming the axial load into an equivalent radial load.

The calculation for a radial or thrust bearing must take account of the following principal factors:

- actual supported loads and possible shock loads
- speed of rotation
- operating temperature
- hardness of the bearing raceways.

Other features such as lubrication, sealing and alignment must be considered in order to avoid introducing unfavourable factors.

The formulas for lifetime calculations here reported are considered valid under standard conditions, generally useful for first-sizing or product comparison.

For further details on correction factors for bearing lifetime in applications, please refer to ISO281 and ISO16281 standards and to Nadella Technical Service. The life calculation of a radial bearing or a thrust bearing under rotation is established from the dynamic capacity C indicated in the tables of dimensions. The static capacity Co enables one to determine the maximum load under certain operating conditions (see table on page 8).

### 3.1. BEARING LIFETIME

#### 3.1.1. Dynamic capacity C

The dynamic capacity of a bearing is the constant radial load which it can support during one million revolutions before the first signs of fatigue appear on a ring or rolling element. For a thrust bearing, the capacity for one million revolutions assumes a constant axial load centred in line with the axis of rotation.

The dynamic capacity is a reference value only; the base value of one million revolutions has been chosen for ease of calculation. Since applied loading as great as the dynamic capacity tends to cause local plastic deformations of the rolling surfaces that may affect their operations.

The dynamic capacity C for bearings shown in the tables of dimensions has been established in conformance with the ISO Standard 281.

#### 3.1.2. Nominal life $L_{10}$

The life of a (or thrust bearing) is the number of revolutions (or the number of hours at constant speed) that it will maintain before showing the first signs of material fatigue.

The relationship between the life in millions of revolutions  $L_{10}$ , the dynamic capacity C and the supported load P, is given by the formula:

$$L_{10} = \left( \frac{C}{P} \right)^{\frac{10}{3}}$$

in this expression p is equal to 10/3 for needle or roller bearings. In order to assess the importance of the influence of load on the life expectancy, one should note for example that, if the load on a bearing is doubled, its life is reduced by a factor of 10. The formula above is independent of speed of rotation which must not exceed the recommended limit in respect of the radial bearing or the thrust bearing used and the method of lubrication. If the speed of rotation n (r.p.m.) is constant, the life is given in hours by the function:

$$L_{10n} = \frac{L_{10} \times 10^6}{60n}$$

The above formula will ensure that 90% of the bearings operating under the same conditions will attain at least the calculated  $L_{10}$  life, known as the nominal life (the figure 10 being the percentage of bearings which may not attain this life). The formulae are based on the use of standard quality bearing steel and assume a satisfactory method of lubrication.

The formulas for life calculation are effective for an applied load smaller than 0.5 C.

# Technical features

## 3.1.3. Modified life $L_{na}$

In conditions different from the mentioned above, a modified life  $L_{na}$  can be determined (in millions of revolutions) following the general formula:

$$L_{na} = a_1 \cdot a_{iso} \cdot L_{10}$$

in which  $a_1$  and  $a_{iso}$  are correction factors linked respectively to reliability, contamination and lubrication.

### Reliability correction factor $a_1$

A reliability factor in excess of 90% may be required in certain industries fields, such as aviation, for reasons of security and to reduce the risk of a very costly immobilisation. The table below indicates the values of the correction factor  $a_1$  as a function of reliability:

Reliability %	Factor $a_1$	Modified life $L_{na_1}$
90	1	$L_{10}$
95	0,64	$L_5$
96	0,55	$L_4$
97	0,47	$L_3$
98	0,37	$L_2$
99	0,25	$L_1$
99,5	0,175	$L_{0,5}$
99,9	0,093	$L_{0,1}$

In order to select as an example a bearing of life  $L_4$  (reliability 96%) it is necessary to estimate life  $L_{10}$  with the formula  $L_{10} = (C/P)_{10/3}$  starting from the dynamic capacity C given in this catalogue:

$$L_4 = 0,55 \cdot L_{10}$$

### Correction factor $a_{iso}$

The factors that affect bearing life are numerous, and their analysis is not one in this catalogue. The effects of temperature, misalignment, bearing clearance, cleaning and lubrication conditions, which require a detailed discussion is beyond the scope of the product catalogue. For a more detailed discussion, please refer to Standards:

ISO 281:2007 introducing the coefficient  $a_{iso}$  to take into account the effects of lubrication and cleanliness of the lubricant.

ISO 16281, which introduces in the calculation the effect of clearance and misalignments in the bearing.

Nadella technical service is available for advice on the choices to be made in special cases.

## 3.1.4. Variable loads and speeds

When the loads and speeds are variable, the life calculation can only be made by first establishing an assumed constant load and constant speed equivalent in their effect on the fatigue life.

This type of operating condition is frequently met and the possible variations although cyclical are numerous. One encounters this feature in particular, in variable speed drives on some supports, but constant on each support for an interval of time referring to the total operating time (example: change of speed). The equivalent load P and the equivalent speed n are obtained from the following formulae:

$$P = \sqrt{\frac{m_1 \cdot n_1 \cdot P_1^2 + m_2 \cdot n_2 \cdot P_2^2 + \dots + m_n \cdot n_n \cdot P_n^2}{m_1 \cdot n_1 + m_2 \cdot n_2 + \dots + m_n \cdot n_n}}$$

$$n = m_1 \cdot n_1 + m_2 \cdot n_2 + \dots + m_n \cdot n_n$$

in which:

$m_1, m_2, \dots, m_n$ : interval of operating time under constant load and speed (by definition:  $m_1 + m_2 + \dots + m_n = 1$ ).

$n_1, n_2, \dots, n_n$ : constant speed corresponding respectively to intervals of time

$m_1, m_2, \dots, m_n$ : constant loads corresponding respectively to intervals of time

$P_1, P_2, P_n$ :  $m_1, m_2, \dots, m_n$ .

For needles and rollers bearings and thrust bearings, p is equal to 10/3.

Whilst at constant speed, the load varies linearly during a given time, between a minimum  $P_{min}$  and a maximum  $P_{max}$ . the equivalent load is given by:

$$P = \frac{P_{min} + 2P_{max}}{3}$$

# Technical features

## 3.1.5. Oscillating motion

In order to calculate the life during oscillating motion it is necessary to determine an equivalent speed  $n$  in revolutions per minute from the formula:

$$n = \frac{n_{osc}\alpha}{180}$$

$n_{osc}$ : number of oscillations "Forward and Return" per minute

$\alpha$ : amplitude of oscillation "Forward" in degrees.

However, this formula risks being in error and giving inaccurate lives for oscillations at small amplitudes. It is therefore recommended not to apply it for angles of oscillation below 15°.

When the angle of oscillation is very small fretting corrosion is likely to be produced and a suitable lubricant must be chosen in consequence. Experience confirms that full complement needle bearings provide better results under this phenomenon in view of their better load sharing capability.

## 3.1.6. Application criteria

The life calculation may be unreliable when values for speed and load reach the ultimate limits. A low speed and/or load can yield an extremely long calculated life but this will be limited in practice by other operating factors such as sealing, lubrication and maintenance, all of which have a decisive influence on the life of the product in such cases.

## 3.2. MINIMUM LOAD

Slippage can occur if loads are too light and, if accompanied by inadequate lubrication, cause damage to the bearings. The minimum load for bearings with cage must be

For radial bearings

-  $F_{r\min} = 0,04 C$

(C is the Dynamic Capacity for lifetime calculation)

For thrust bearings are correct the formulas

- Needle bearings  $F_{a\min} = 0,005 C_o$

- Roller bearings  $F_{a\min} = 0,001 C_o$

( $C_o$  is the Static Capacity)

## 3.3. STATIC CAPACITY $C_o$ AND LIMIT LOAD $P_o$

The static capacity  $C_o$  given in the tables of dimensions has been established in conformance with ISO Specification 76. This takes into consideration the maximum admissible contact stress (Hertzian stress). The value currently being adopted in 4000 MPa.

Since permanent deformation is produced as readily in a bearing rotating as in one that is stationary, the static capacity  $C_o$  determines the limit load  $P_o$  which depends on the type of bearing and the operating conditions. When the limit load  $P_o$  is given within the "min-max" range, the load applied may attain the indicated maximum provided it is applied continuously without sudden repeated variations. Alternatively, in the case of shock loads and vibrations, the load applied should not exceed the minimum value of limit load  $P_o$ . The relationship between the static capacity and the limit load defines the safety static factor  $f_o$ :

$$f_o = C_o/P_o$$

The suggested values for the safety factor, depend on the type of application and product

Solid rail bearings

$f_o = 1,5 \dots 2,5$  Important requirements for smoothness of function, silent operation or accuracy of rotation

$f_o = 1 \dots 1,5$  General applications

$f_o = 0,7 \dots 1$  Slow rotation or oscillatory motion.

Drawn bearings

$f_o > 4$  Important requirements for smoothness of function, silent operation or accuracy of rotation

$f_o > 3$  General applications and oscillatory motion

Cam followers: the allowable load for cam followers depends on the static load of the bearing and from the strength of the stud and of the outer ring. Authorised values are listed in the tables of dimensions.

# Technical features

## 3.4. COEFFICIENT OF FRICTION

The resistance torque M of a bearing supporting a load P is given by the following relationships:

- Radial bearing:  $M = f \cdot P \cdot \frac{F_w}{2}$

(with  $F_w$  is the diameter of the inner raceway of the bearing)

- Thrust bearing:  $M = f \cdot P \cdot \frac{dm}{2}$  with  $dm = \frac{E_b + E_a}{2}$

( $E_b$  and  $E_a$  being the internal and external raceway diameters given in table of dimensions).

The coefficient of friction  $f$  depends on a number of factors, amongst which are:

- type of mechanism
- applied load
- speed of rotation
- lubrication
- surface finish and alignment of raceways.

The mean values shown below are for oil lubrication

$f = 0,002 \div 0,003$  for caged needle bearings

$f = 0,003 \div 0,004$  for full complement bearings and needle thrust bearings

$f = 0,004 \div 0,005$  for roller thrust bearings.

These coefficients are applicable for values of C/P between 2 and 6 approximately. For values less than or in excess of these limits the coefficient of friction  $f$  can be increased by 10 to 50%. Under starting conditions from rest, the values of  $f$  may be up to 1.5 times higher than those shown above.

To evaluate the losses of the entire bearing assembly, account must also be taken of the friction due to the seals which can be significant, especially during "running-in".

## 3.5. LIMITING SPEED

The tabular pages list the limiting speed values calculated under normal operating conditions, properly mounting tolerances and clearance, absence of misalignments, low loads. For speed calculated with oil lubrication it is considered a normal flow of lubricant. A bearing may operate at a speed higher than the listed limiting speed with use of a clean, with good quality oil and correct flow to remove the heat generated in the table. Consult Nadella Technical Service for further details.

In case of high speed and acceleration to avoid internal slippage between the rolling elements and the raceways the relationship between the applied load  $P$  and the base load of the bearing  $C$  must be at least  $P/C > 0.02$ . The wheels are supplied normally lubricated with grease suitable for general use, so the limit speed given in the dimension tables take account of such lubrication. For wheels without seals, lubricated with oil, the indicated speed limit may be increased by about 30% for continuous rotation (about 50% for intermittent rotation).

# Technical features

## 4. MOUNTING

### 4.1. SHAFT FOR BEARINGS WITHOUT INNER RING

#### 4.1.1. Heat treatment of raceways

The minimum hardness of 58-64 HRC required to apply the calculations without reducing the basic capacities may be obtained with a through-hardened bearing steel or with a case-hardened and tempered steel. In the latter case, the hardened case must be homogeneous and regular over the entire surface of the raceway: the case depth is the thickness between the surface and the core having a hardness value of Vickers HV1 of 550 (see Standard NF A 04 202).

The minimum effective case depth of hardening depends on the applied load, the size of the rolling elements and the core strength of the steel used. To calculate the approximate case depth minimum depth can be used the following formula

$$\text{Minimum case depth} = (0,07 \div 0,12) \times D_w$$

D<sub>w</sub> = diameter of the rolling element

In any case the minimum suggested case depth is of 0.4 mm.

The load capacities shown in the tables of dimensions apply to raceways with a hardness of between 58 and 64 HRC.

The dynamic and static capacities are reduced when hardness values are lower than 58 and 54 HRC respectively according to the following table:

Hardness	HRC	60	58	56	54	52	50	48	45	40	35	30	25
	HV*	697	653	613	577	545	512	485	447	392	346	302	267
Coefficients for load reduction	Dyn.	1	1	0.93	0.84	0.73	0.63	0.52	0.43	0.31	0.23	0.15	0.11
	Stat.	1	1	1	1	0.96	0.86	0.77	0.65	0.50	0.39	0.30	0.25

#### 4.1.2. Surface finish

The shafts or housing used directly as raceways for needles must have a surface finish acceptable for the operating conditions and the precision requirements:

- applications with high speeds and loads: Ra = 0,2 µm
- general applications: Ra = 0,35 µm

#### 4.1.3. Tolerances and form deviations

The suggested tolerances for the mean shaft diameter are indicated in the appropriate chapters specific for every product.

The suggested tolerance for deviation from the cylindrical raceways form (radial bearings).

- Variation of mean shaft diameter within the length of the bearing raceway should not exceed 0.008 mm or one-half the diameter tolerance. The profile should never be concave (the core diameter must protrude to the diameter at the ends)
- Deviation from circular form: the minimum between 0.0025 mm and one quarter of diameter tolerance

For thrust bearings and combined bearings refer to the specific chapter prescriptions.

#### 4.1.4. End chamfer

For the most effective assembly and preventing damage to the roller complements or needles, provide a chamfer to the ends of the raceway.

#### 4.1.5. Surface in contact with seals

The surface in contact with the sealing lips must be finished with plunge cut grinding. The propeller subsequent to the grinding process without centers can create a pumping effect of the lubricant through the seal.

## 4.2. SHAFT FOR BEARINGS WITH INNER RING

### 4.2.1. Surface finish of the shaft

Maximum roughness suggested: Ra = 1,6 µm

#### 4.2.2. Tolerances and form deviations

The suggested tolerances for the mean shaft diameter are indicated in the appropriate chapters specific for every product.

The suggested tolerance for deviation from the cylindrical raceways form (radial bearings)

- Variation of mean shaft diameter within the length of the bearing raceway: one-half of the diameter tolerance
- Deviation from circular form: one-half of the diameter tolerance

#### 4.2.3. End chamfer

For the most effective assembly provide a chamfer to the ends of the shaft on which the inner ring must be inserted.

# Technical features

## 4.3. HOUSING FOR BEARINGS WITH OUTER RING

### 4.3.1. Surface finish of the shaft

Maximum roughness suggested: Ra = 1,6 µm

### 4.3.2. Tolerances and form deviations

The suggested tolerances for the housing is indicated in the appropriate chapters specific for every product.

The suggested tolerance for deviation of form is

- Variation of mean housing diameter within the length in contact with needle: 0.013 mm
- Deviation from circular form: one-half of the diameter tolerance of the housing

### 4.3.3. End chamfer

For the most effective assembly provide a chamfer to the ends of the shaft on which the inner ring must be inserted.

### 4.3.4. Alignment between hole housing

When possible ream the housing of the same shaft with a single placement on the machine tool.

## 4.4. HOUSING FOR CAGES AND NEEDLES

### 4.4.1 Requirements for materials, processing and finishing

Observe the rules for the shafts, paragraph 4.1.

### 4.4.2. Alignment between hole housing

When possible ream the housing of the same shaft with a single placement on the machine tool.

## 5. LUBRICATION

Bearings are protected against oxidation with a corrosion protection, but normally supplied unlubricated. Please don't forget to lubricate them when mounting.

### 5.1. LUBRICANT FEATURES

Lubrication of a bearing provides a viscous film between the rolling elements in order to reduce heat and wear caused by friction. The lubricant can also assist in preventing corrosion and help to seal the bearing from the introduction of dirt and impurities; it reduces friction between the shaft and seals and lowers the noise level generated within the bearing.

Wherever the operating conditions permit, grease should be chosen in preference to oil, as it is more convenient to use and more economic. Furthermore, it acts as an efficient seal against the effects of dust and humidity. On account of its consistency, grease can improve the effectiveness of sealing rings and can be used on its own as a seal, when it is used to fill grooves or labyrinth provided for this purpose.

Alternatively, oil is necessary for high rotational speeds in excess of the limits advised for grease lubrication and in cases where there is a problem of heat dissipation. Oil can also remove moisture and impurities from the bearing and is usually easily controlled to monitor the state of lubrication. Oil lubrication is also necessary where it is used already in the function of the equipment, such as hydraulic motors and pumps, speed variators and gear boxes etc.

Oil and grease lubricants must be free of all impurities which could cause premature failure of the bearing and removal from service. Sand and metal particles are particularly injurious to bearings. Every precaution must be taken to assure the cleanliness of gear casings, pipes, grease nipples, couplings, as well as lubricant containers.

The efficiency of a lubricant decreases in service both by age and by the continuous mixing to which it is submitted. Therefore replenishment must take place at regular intervals, taking account of operating and environmental conditions (humidity, dirt, temperature) except for applications where the bearing has been lubricated for life with a suitable grease.

# Technical features

## 5.1.1. Base oil

It is the main constituent of a lubricant, being it an oil (obtained by adding base oil to chemical additives) or a grease (which is obtained by adding the thickener to the oil). Technically base oils differ between them for their chemical/physical properties and for their ability to work in particular conditions such as high temperatures or low temperatures or even in oxidizing environments, and so on.

The following table shows the main base oils and their main physical features distinguishing its capabilities.

Parameter	Mineral oil	Ester based oil	Polyglycol oil	Silicone oil	Fluoro-carbon oil
Density [g/ml]	0.9	0.9	0.9-1.1	0.9-1.05	1.9
Viscosity index VI (1)	100	150	>200	200/500	50/150
Pour Point [°C] (2)	-10/-40	-30/-70	-20/-50	-30/80	-30/-70
Flash point [°C] (3)	200/250	230/300	150/300	150/300	No one
Oxidation resistance	Sufficient	Good	Good	Excellent	Excellent
Temperature stability	Sufficient	Good	Good	Excellent	Excellent
Lubricating ability (4)	Good	Good	Excellent	Low	Good
Compatibility with seals	Good	Low	Sufficient	Good	Good

- (1) The viscosity index represents the ability of the lubricant to maintain constant its viscosity with changes in temperature; An high value of index VI means good ability to maintain a constant viscosity (key parameter for oils).
- (2) The pour point is the lowest temperature at which the lubricant loses the ability to scroll (solidification), so it is an index for the utilization of the lubricant at low temperatures.
- (3) Minimum temperature at which the air / gas mixture above the lubricant will ignite if it gets too close to a heat source.
- (4) The lubricating ability indicates the ability of the lubricant to withstand large loads applied.

The mineral oils are used in most applications. Synthetic oils (such as esters, polyglycols, silicon) and finally the fluorocarbon that are special oils as chemically inert (due to the presence of fluoride) in the case of specific needs.

It is important to note the general rules on the viscosity of the oils:

- fluid oil = excellent refrigerant;
  - thick oil = excellent lubricant;
- never use a lubricant with a viscosity greater than necessary.

## 5.1.2. Additives

The addition of additives to the base oil, allows to obtain an oil with performance features clearly higher than the base oil itself. The additives allow to reduce some negative sides of base oils, although a silicone oil (particularly weak to support applied loads) suitably additized (eg with EP additives) will never be as a synthetic oil or polyglycol .

The following table shows the main technological characteristics related with additives.

Additives	Features
Anti-oxidants	They slow down the oxidation that creates deposits on the surfaces in contact with detriment to the lubricating fluid that deteriorates
Anti-corrosion	Slow chemical reactions with materials such as copper, aluminum and sulfur
Anti-rust	Slow down the chemical reactions with ferrous materials that give life to rust
Anti-wear	Slow down the wear phenomena of materials in contact with the lubricant
EP	Extreme Pressure it allows to increase the ability of the lubricant to withstand the applied load thereby reducing the danger of seizure
Detergents	Clean the metal surfaces from debris or oxidation products by emulsion
Dispersants	Maintain the oxidation and emulsion products in suspension, preventing their deposit on metal surfaces
Pour Point	Lower the flow temperature of a lubricant allowing its use at low temperatures
Enhancers of VI	Increase the viscosity index allowing to obtain a lubricant constant in a wide range of temperature. Used mainly to the extreme temperatures temperature
Anti-foaming	Reduce the danger of the formation of foam in the lubricant
Adhesiveness enhancers	Increase the adhesion of the lubricant to the surface with which it is in contact
Compatibility with seals	Good

# Technical features

## 5.2. GREASE LUBRICATION

Greases for bearings must possess high lubricity power, good mechanical stability, an effective oxidation resistance and good anti-rust features, especially for parts operating in humid environment or subjected to splashing water. Their consistency, generally of grade 1, 2 or 3 of the NLGI scale, must remain as stable as possible within the temperature limits allowed by their composition.

### 5.2.1. Main types of grease

The grease is a thick lubricant, it consists of the base oil, plus additives and a thickener which is very often composed of a soap.

Greases based on lithium soap are particularly suitable for the lubrication of needle and rollers bearings and thrust bearings. They can be used at operating temperatures between -30 and +120°C, and even up to 150°C if they are of good quality. They are generally fitted with anti-rust additives and offer a good protection against corrosion.

Greases based on sodium soap are suitable for the lubrication of the bearings up to approximately 100°C (minimum temperature -30°C) and ensure a good seal against dust. They can absorb small amounts of water without losing their lubricating properties, but high amounts of water will dissolve and cancel all their effectiveness.

Greases based on calcium soap are stable to water and can be used only up to 50 or 60°C. Their mechanical stability and their power anti-rust are weak. Their use as lubricants for bearings is therefore not recommended, but may be used in labyrinth seals. However, some grease calcium based, with increased mechanical stability and anti-rust power, can be used up to 100°C to lubricate bearings in a humid atmosphere.

	Lithium soap	Sodium soap	Calcium soap	Polyurea	Lithium aluminium complex soap
Temperature range	120	110	60	160	160
Drop point	190	260	100	230	260
Water resistance	Good	Low	Excellent	Excellent	Good
EP capacity	Good	Good	Good	Low	Excellent

### 5.2.2. Consistency

The parameter that determines the softness or hardness of the grease is the consistency, that is, the penetration of the lubricant. It is defined by the NLGI consistency scale of measurement, according to eight levels which corresponds to a range of values of the Worked Penetration, expressed in tenths of millimeter.

The following table shows the classes defined by the NLGI consistency.

NLGI class	Worked Penetration	Texture
000	445 – 475	Liquid
00	400 – 430	Semi-liquid
0	355 – 385	Very very soft
1	310 – 340	Very soft
2	265 – 295	Soft
3	220 – 250	Medium
4	175 – 205	Hard
5	130 – 160	Very hard
6	85 – 115	Extremely hard (as softwood)

### 5.2.3. Special grease

Greases with **EP additives** (high pressure) can be useful when bearings or thrust bearings must work with heavy loads. These greases generally offer a good lubricating power and have good anti-rust properties even in the presence of moisture. EP additives are used in the case of bearings with high load and low rotation speed, insufficient to create a meatus of lubricant sufficient to separate the metal parts.

Greases for **low temperatures**. The starting torque at low temperatures can be problematic. Suitable acids are commercially available.

Greases for **high temperatures**. The stability and duration of the grease is strongly influenced by temperature. In general the standard greases can be used up to 120°C-150°C. Further should be provide specific products. For high temperatures can be used lubricating pastes.

## 5.2.4. Compatibility of greases

Certain greases are incompatible with others and, if they are mixed, their function will be impaired.

With greases considered as compatible, account should be taken of the reduction in their consistency when mixed and the maximum permissible temperature should be reduced accordingly.

## 5.2.5. Application

Grease can be introduced into the bearings at the time of assembly, care being taken to distribute it around the crown of the needles (see below "Quantity of grease"). The free space found in the bearing which is filled with grease, constitutes a reservoir and a reinforced seal. This method is possible if replenishments of grease are necessary at regular maintenance periods, during the course of which one can dismount the bearings, clean and examine them. Otherwise one has to use a hand pump which forces grease into the bearing by means of valves and replenishes the adjacent reservoir and also the channels and labyrinth seals.

The entry passage for the grease must directly abut the bearing or be in close proximity to it, in order that new fresh grease pushes out the used grease through the seals. For this reason the lip of the sealing ring must be oriented towards the outside of the bearing for it to rise under the force of the grease being ejected. This method has the advantage of removing impurities which could be introduced into the seals, particularly in the case of a highly contaminated atmosphere.

## 5.2.6. Quantity of grease

The amount of grease that should be contained in a bearing can be established by considering the relationship of the limiting speed permissible for the grease  $n_G$  to the speed of rotation  $n$ :

- $n_G/n < 1,25$  minimum quantity; bearing must be lubricated with a small quantity of grease and the adjacent parts packed with grease
- $1,25 < n_G/n < 5 \frac{1}{3}$  to  $2/3$  of the available volume
- $n_G/n > 5$  bearing must totally filled with grease.

# Technical features

## 5.2.7. Re-lubrication

The frequency of grease re-lubrication depends on a number of factors, amongst which are the type of bearing and its dimensions, the speed and load, the temperature and ambient atmospheric conditions (humidity, acidity, pollution), the type of grease and sealing.

Only after controlled trials can the re-lubrication period be defined exactly and particular importance should be given to the effects of temperature, speed and humidity. Under normal conditions of function without unfavourable factors using an appropriate grease with a maximum temperature of 70°C, the re-lubrication interval  $T_G$  in hours can be determined approximately from the formula:

$$T_G = \frac{K \times 10^6}{n \times \sqrt{F_w} \times \sqrt[4]{\frac{n}{n_H}}}$$

n: speed of rotation

$n_H$ : permissible speed limit for grease lubrication (see page 14)

$F_w$ : diameter of inner raceway of bearing in mm

K: coefficient according to the type of bearing:

K = 32 for caged needle bearings K = 28 for full complement needle bearings K = 15 for needle or roller thrust bearings.

For the bearings below, the diameter  $F_w$  is replaced by the following dimensions, given in the table of dimensions:

Cam followers type FG and derivatives: dimension  $d_A$

Needle or roller thrust bearings: dimension  $E_b$

Cam followers type GC and derivatives:

average dimension  $\frac{d+d_A}{2}$

If the operating temperature exceeds 70°C, the interval  $T_G$  determined from the formula above should, for each increase of 10°C, be reduced by 50%. However, this adjustment is not applicable beyond 115°C; for temperatures above this level trials should be made to determine the acceptable re-lubrication interval.

In the case of very slow speed rotation, which would give interval  $T_G$  in excess of 35000 hours corresponding to 8 years operation at a rate of 12 hours per day, it is recommended to limit the period to a maximum of 3 years. For oscillating motion, the speed to be considered is the equivalent speed given by the formula on page 11. For very small amplitudes of oscillation it is recommended to reduce by half the calculated re-lubrication period  $T_G$ .

## 5.3. OIL LUBRICATION

### 5.3.1. Viscosity

The essential characteristic of an oil is its basic kinematic viscosity in mm<sup>2</sup>/sec. at a reference temperature of 40°C according to ISO 3448.

The base viscosity  $V_{40}$  should be increased proportionately as the operating temperature increases but decreased as the speed increases, without however reaching a lower limit below which the film strength of the oil is impaired. For applications under moderate load without shocks up to about 1/5 of the dynamic capacity of the bearing, the viscosity  $V_F$  at the operating temperature should not be lower than 12 mm<sup>2</sup>/sec. For higher loads greater than 1/5 of the dynamic capacity the min. viscosity  $V_F$  can be about 18 mm<sup>2</sup>/sec. The variation in viscosity of an oil as a function of temperature is reduced as the number measuring its index of viscosity is increased. A viscosity index of 85 to 95 is generally satisfactory for the lubrication of bearings.

Diagram 1 below gives the viscosity  $V_F$  required at the operating temperature from the ratio  $n_H/n$  ( $n_H$ : permitted speed limit for oil lubrication - n: speed rotation) and of the applied load (ratio C/P).

For the viscosity  $V_F$  required in operation and from operating temperature, diagram 2 gives the base viscosity  $V_{40}$  at the reference temperature of 40°C.

Example: A bearing supporting a load  $P>C/5$  and having a speed limit for oil lubrication of 10000 r.p.m., must rotate at 2000 r.p.m. at temperature up to 60°C.

$$\text{The ratio } \frac{n_H}{n} = \frac{10.000}{2.000} = 5$$

indicates a viscosity in operation  $V_F = 60$  mm<sup>2</sup>/sec. (diagram 1). For an operating temperature of 60°C, the horizontal  $V_F = 60$  cuts the vertical of 60°C (diagram 2) in the 150 zone, which is therefore the base viscosity required at 40°C.

# Technical features

## 5.3.2. Application of the lubricant

Oil must be supplied to the bearings regularly and in sufficient quantity but not abundantly, otherwise an abnormal increase in temperature can occur. According to the speed of rotation, the following general lubrication methods can be applied:

**Lubrication by oil bath:** is suitable for assemblies with the shaft horizontal and average speeds up to about half the values shown in the tables of dimensions. The level of oil in the bath at rest must reach the lowest point of the inner raceway of the bearing, though the movement of oil caused by the immersion of parts in the oil bath may be sufficient to feed bearings situated above this level, providing there are pipes and collectors to ensure sufficient oil reserve when starting.

**Forced lubrication:** the circuit is typically composed of the tank, the circulation pump, hoses and fittings, filter, possibly the radiator. Allows to effectively lubricate the bearings even in case of high speed, remove dirt and moisture from the bearing, if necessary to remove the heat generated in the bearing.

For the thrust bearing, the arrival of the oil must be made, if possible, from the shaft to use the effect of centrifugation in the sense of movement.

**Oil mist lubrication:** consists of applying to the bearings oil finely atomised in suspension in a current of clean compressed air. The pressure created within the bearing

effectively protects it from the introduction of dust, humid vapours and noxious gases. This procedure, which allows a substantial flow from a small quantity of oil, is used particularly for ultra-high speed applications in excess of speed limits given in the tables of dimensions.

## 6. BEARINGS STORAGE

With the exception of cam followers which are delivered lubricated with grease, all other needle or roller bearing products are supplied without grease, though protected against oxydation by an oil film compatible with most greases and mineral oil lubricants. Bearings should be stocked in a clean dry environment and retained in their original wrapping until the last moment before assembly. Even when assembling the bearing, care should be taken to prevent contamination from dirt or metallic particles and humidity.

In case of doubt concerning cleanliness of the bearing, it may be necessary to wash it in filtered petroleum. In so doing the bearing must be rotated and then suitably drained and dried. Smear the bearing with a suitable oil or grease to protect it against oxydation at the time of assembly.

**Avoid the use of compressed air** to clean or dry the bearing.

And to avoid the risk that a needle roller can be removed from its place and launched (danger for the operator and the people close to him), and because the air introduces moisture into the component.

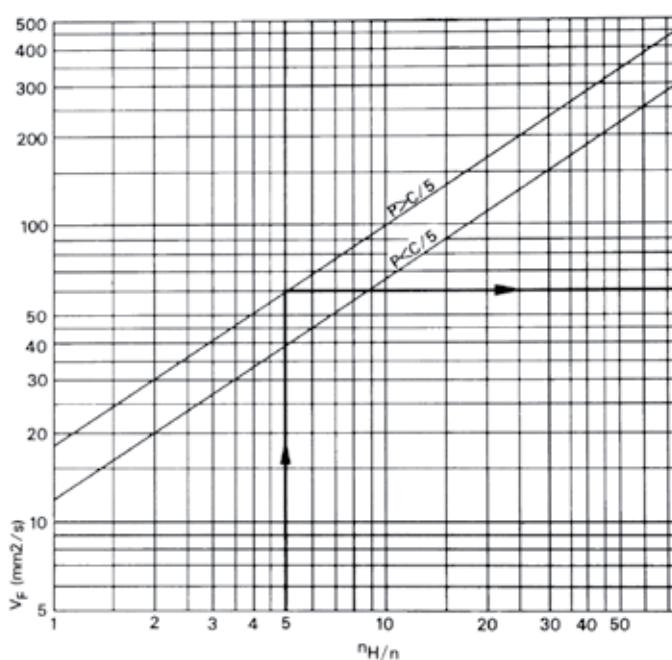

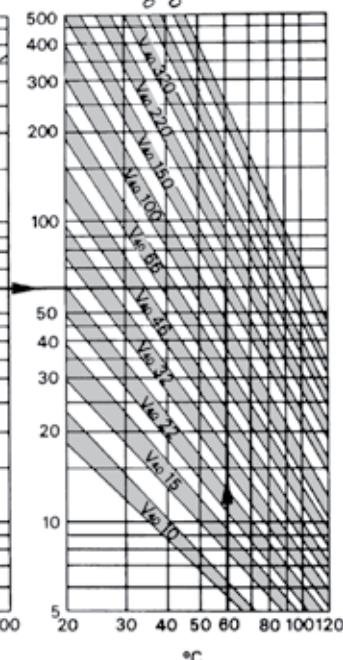

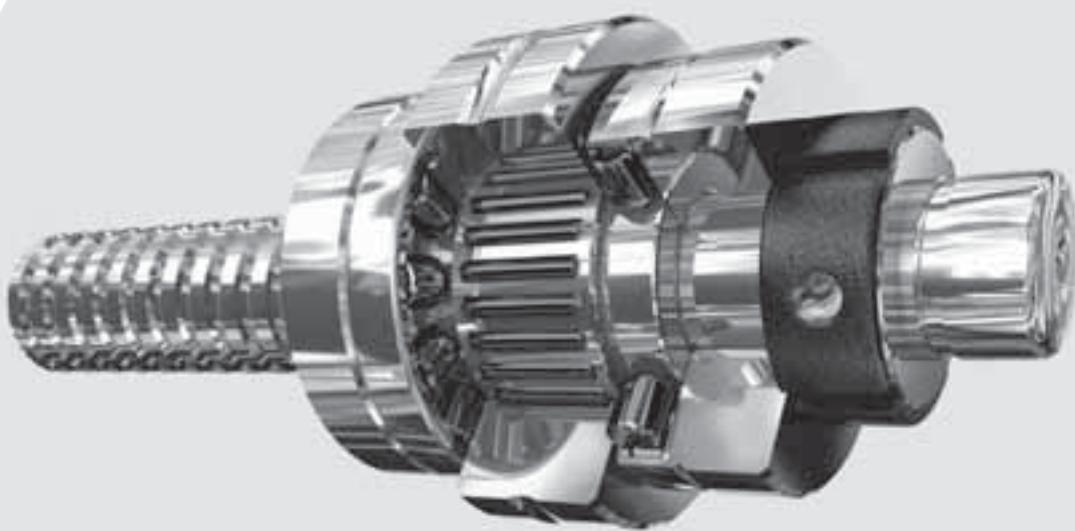

Diagram 2

# APPLICATIONS

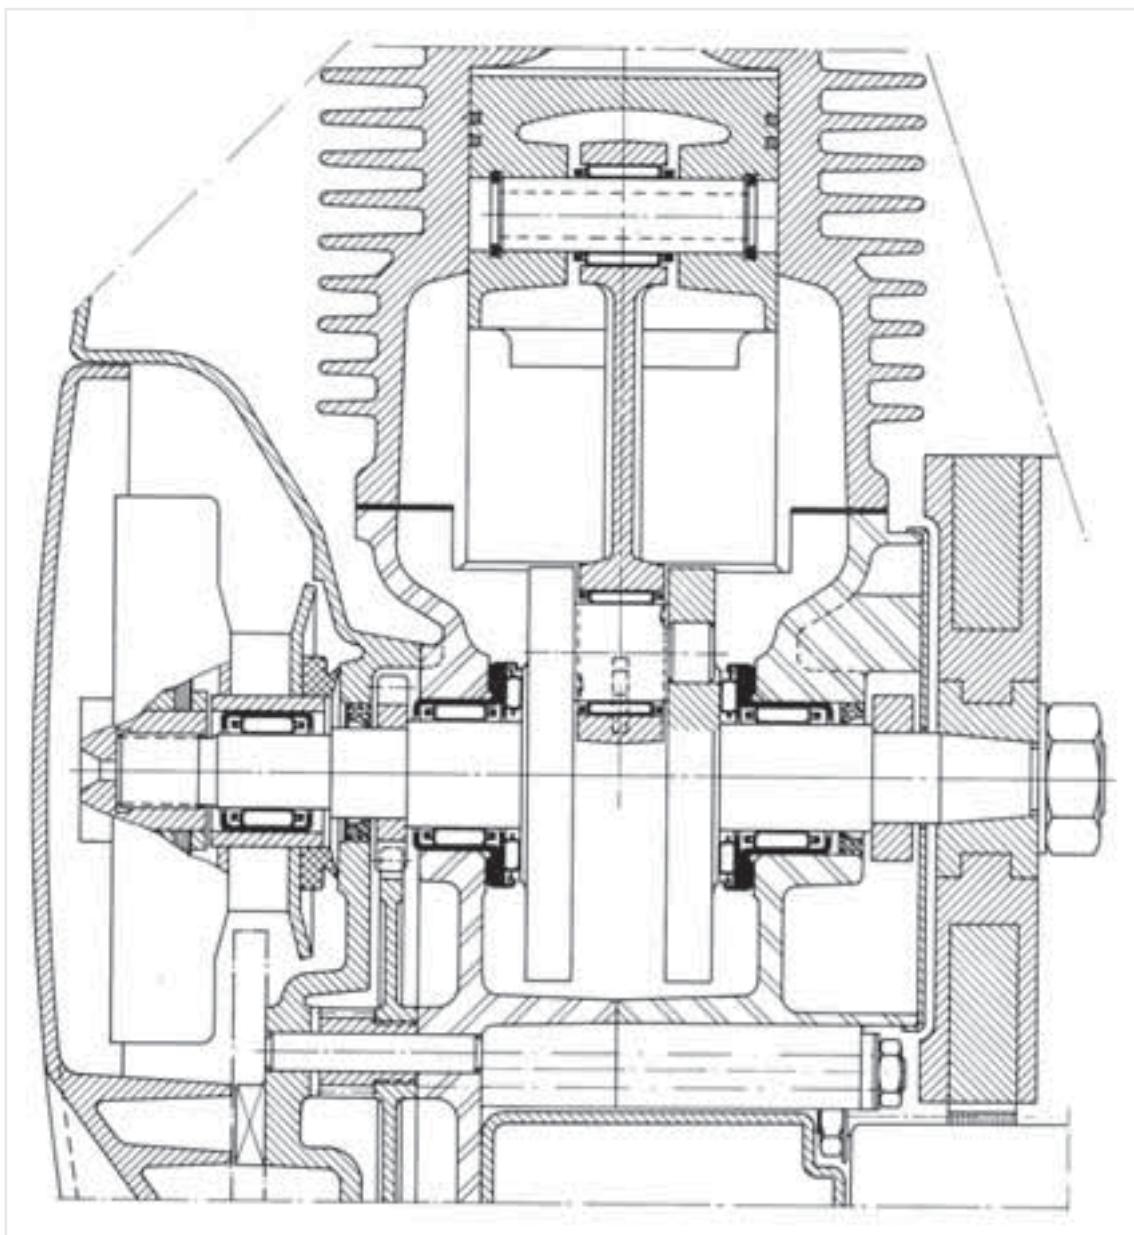

APPLICATIONS

NADELLA

# Applications

## TWO STROKE ENGINE FOR PORTABLE SAW

The high speeds attained by these engines subject the connecting rod bearings to extremely arduous working conditions, made worse by doubtful lubrication and high operating temperatures. Needle cages provide the solution to these difficulties, by virtue of their small size and special manufacturing methods. In the big end of the connecting rod, the steel cage is specially treated and is centred on its outside diameter.

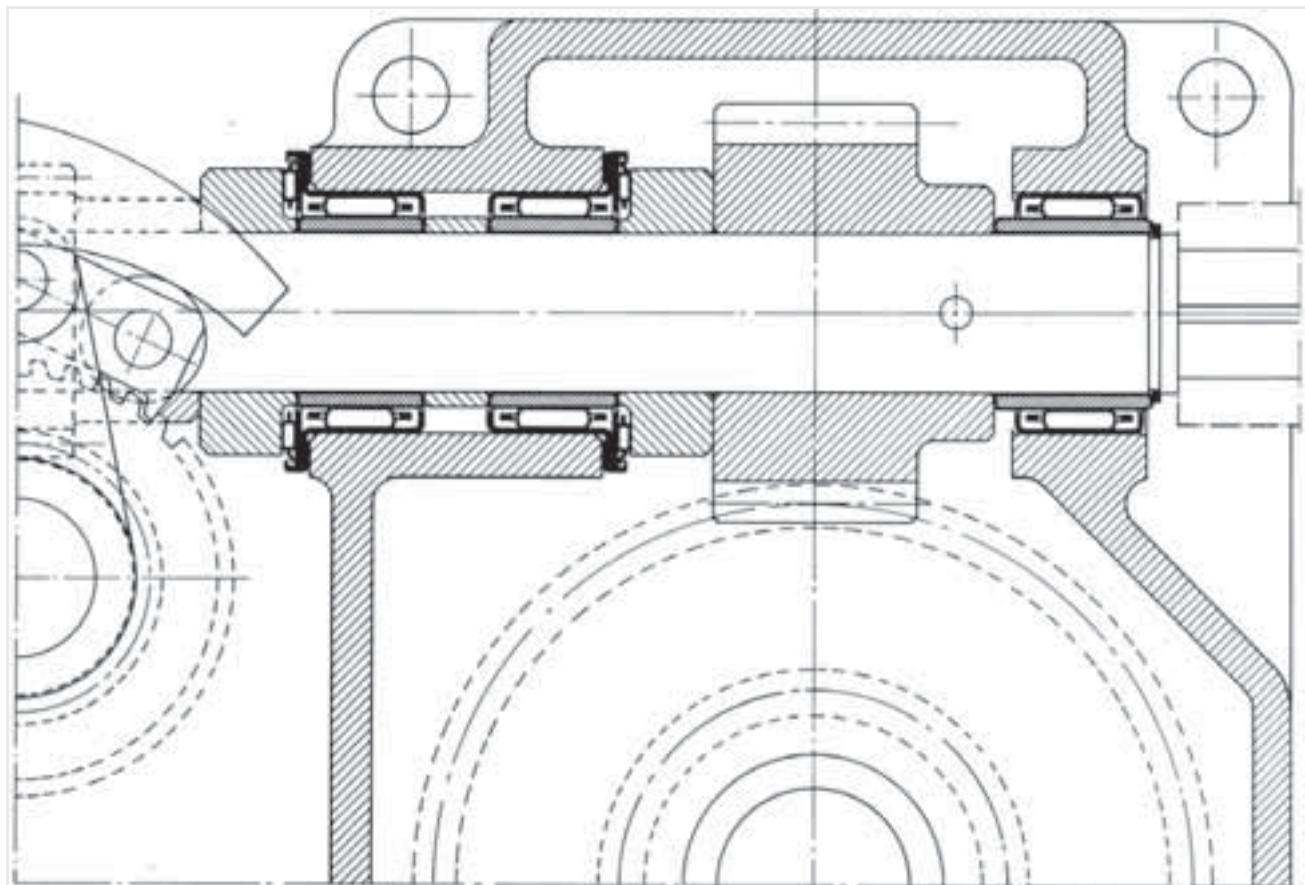

In the little end, on the other hand, the needle cage is centred internally on the gudgeon pin. The cage extends beyond the width of the rod, thereby allowing the maximum possible length of needle to be utilised with consequent reduction of unit load.

Lateral location of the rod is ensured by the crankshaft webs, giving adequate clearance between the little end and the internal bosses of the piston.

The crankshaft runs in two RAX 714 combined bearings to carry the radial loads and provide axial location in the least possible space. They are sealed by two DH lip seals. In the disengaged position, the pulley is supported by a HK 10 12 caged Needle Bushes. All faces and shafts acting as needle raceways are case hardened to 58 – 60 HRC.

# Appliations

## OFFSET PRESS- PAPER FEEDING MECHANISM

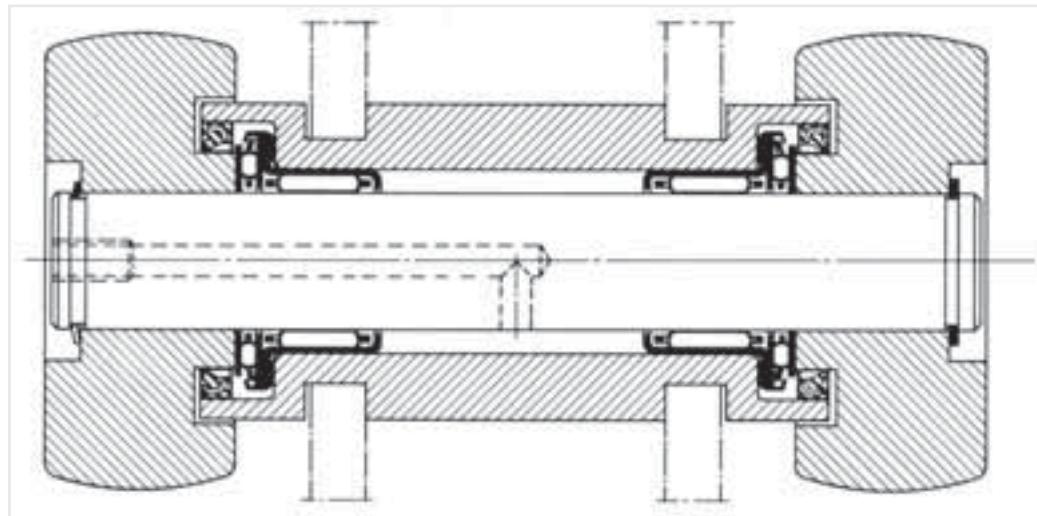

The pinion shaft is supported at one end, by two RAX 730 thin wall combined bearings, which ensure lateral location in both directions. The other end of the shaft runs in a HK 30 20 caged needle bushes.

The use of inner race avoids the necessity for hardening the shaft journals.

# Appliations

## FOLLOWERS FOR OVERHEAD CONVEYOR

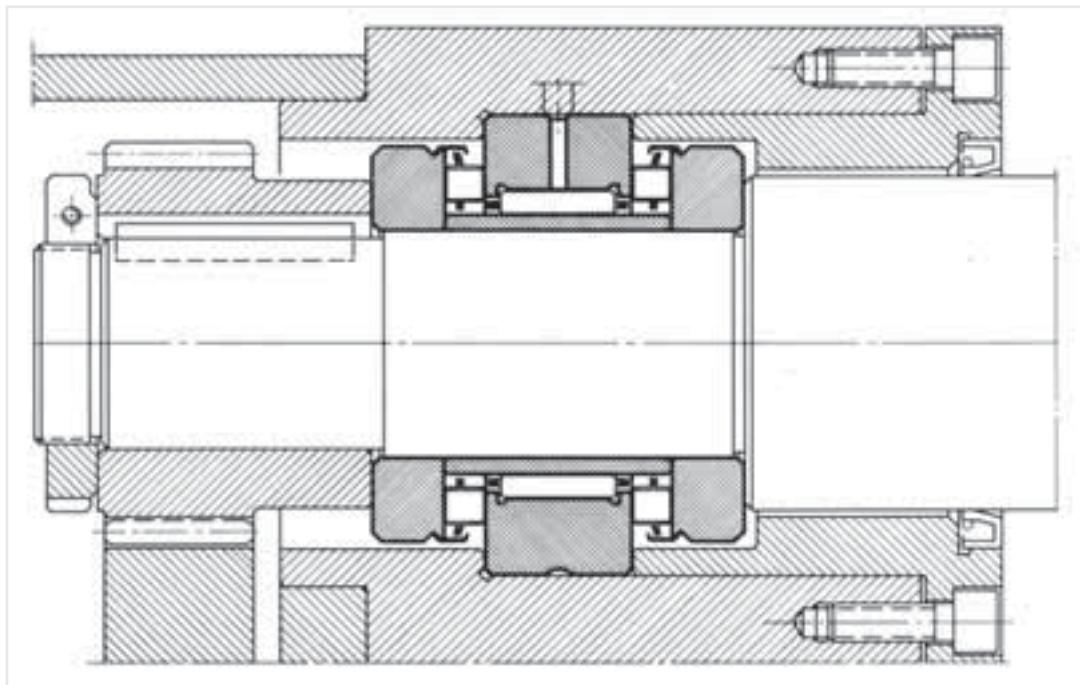

The common spindle carrying the two rollers turns between two RAX 718 combined bearings (with thrust plates) which ensures lateral location in both directions. The bearing surfaces of the shaft are hardened to 58 HRC.

Lubrication is by grease introduced via a nipple on the end of the shaft.

Sealing is effected by sealing rings type DH28x35x4.

# Applications

## LEAD SCREW BEARING FOR AUTOMATIC LATHE

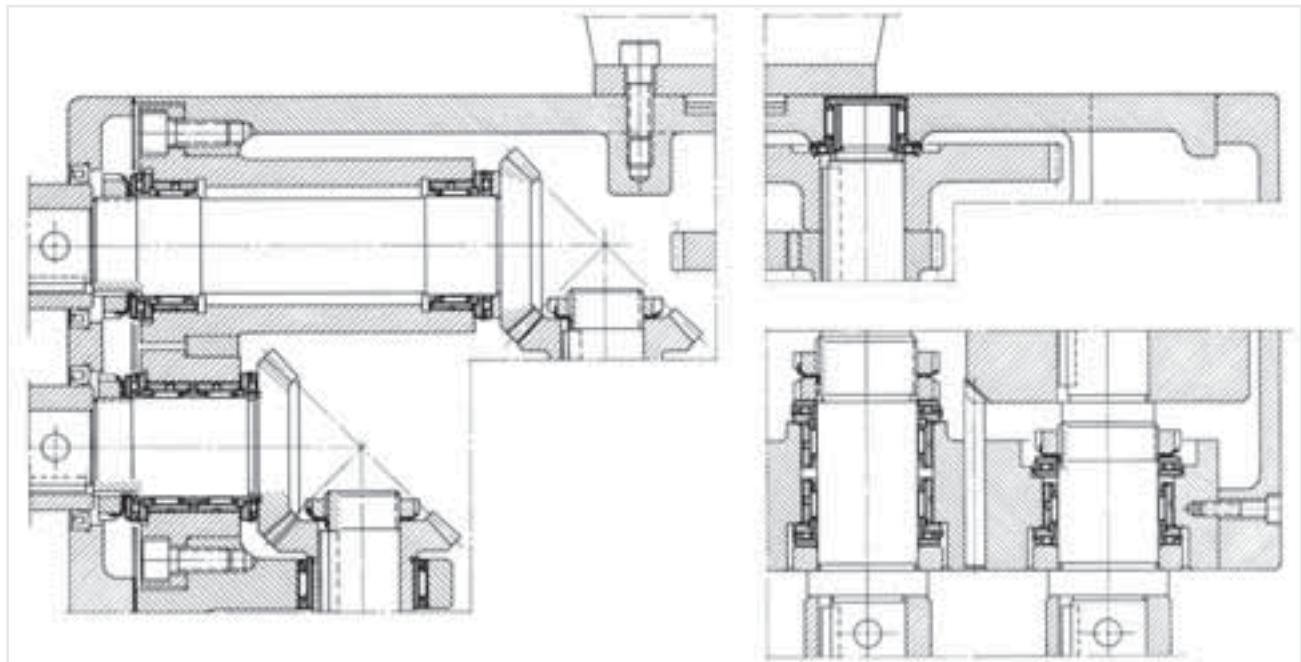

For this application, Nadella has introduced a special precision combined bearing type ARNB ensuring the axial rigidity of the screw, permanently without play, by virtue of the behaviour of thrust races under controlled

preload. This preload, by the lock ring at the end of the pinion, is adjusted precisely to the desired value, whilst assembled, by measuring the torque required to turn the screw, this being a function of the axial loading.

# Applications

## MILLER/BORER - GEAR BOX

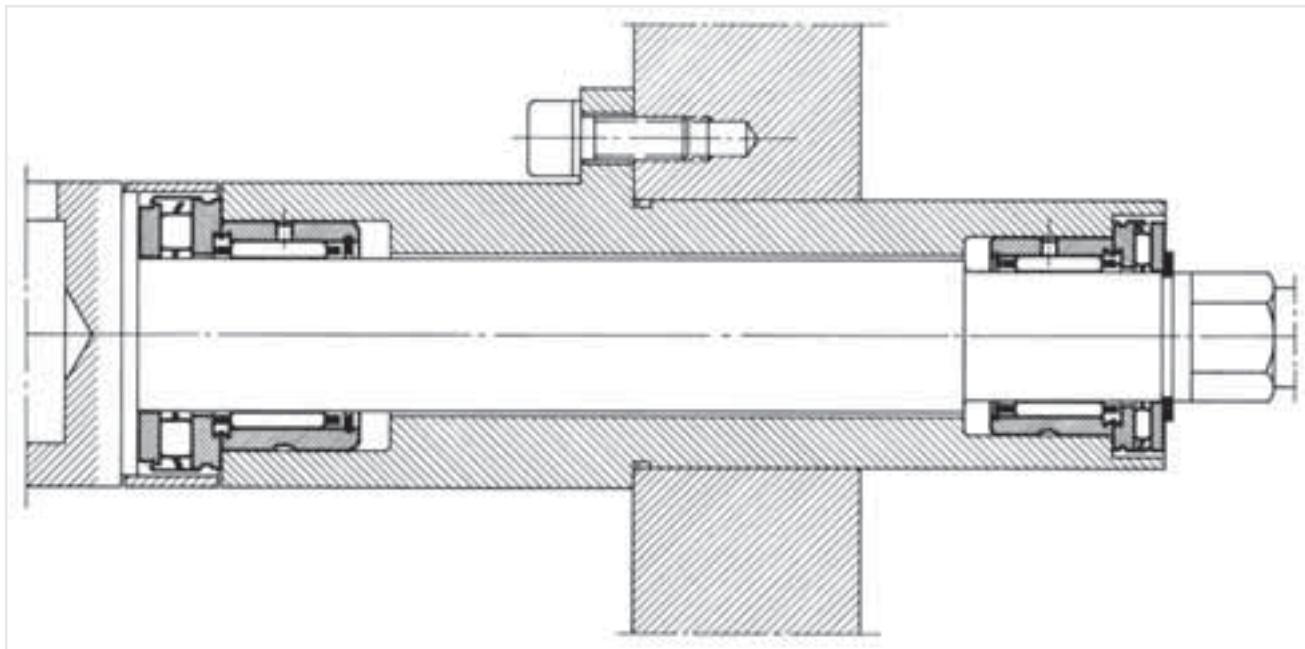

This assembly is particularly interesting in the method of radial and axial location of gears and spindles, by means of two RAX 400 combined bearings mounted in opposition which, even though located in close

proximity, ensure adequate support. Of equal interest is the RAX 700 thin wall combined bearing whose closed end ensures perfect shaft sealing.

# Applications

## BORER SPINDLE

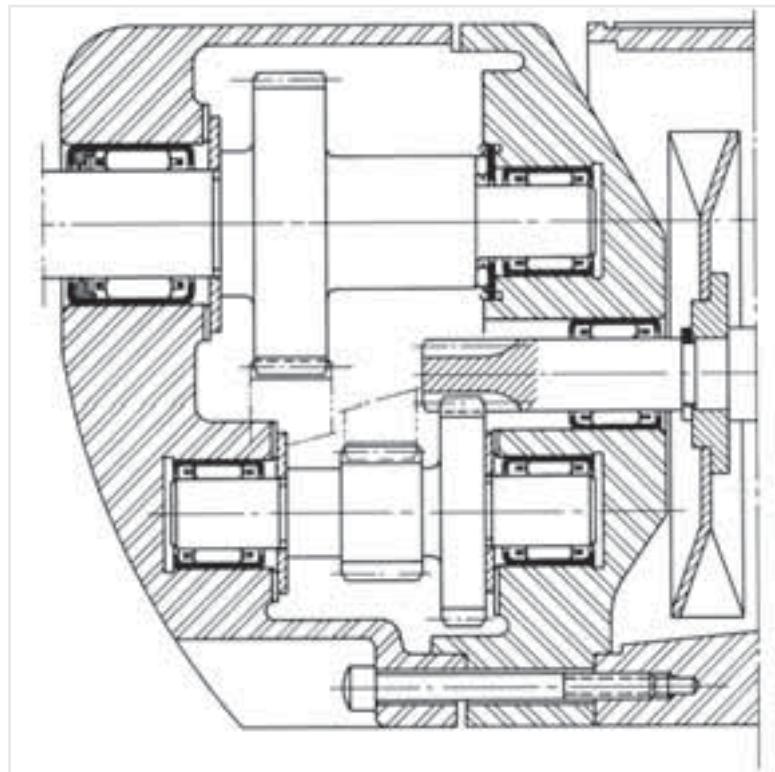

Case hardening the ends of the shaft to 60 HRC allows the use of bearings without inner rings. The front journal is fitted with an RAXZ 520 combined bearing with roller thrust and integral thrust washer. The inside diameter of the radial part of the bearing is held to tolerance F6, and the shaft to k5, giving the necessary low play for this precision application.

The thrust rollers of the combined bearing withstand the main axial loading. It is shielded from ingress of foreign

bodies by the cover which retains the thrust washer and by a sleeve over the assembly. The rear housing incorporates an RAX 417 combined bearing (with thrust washer CP 2 17 30) on a k5 shaft. the needle thrust taking the axial loadings in the opposite direction to the main working load. A speed of 1 500 r.p.m. allows the use of grease for lubrication.

# Applications

## HAND DRILL

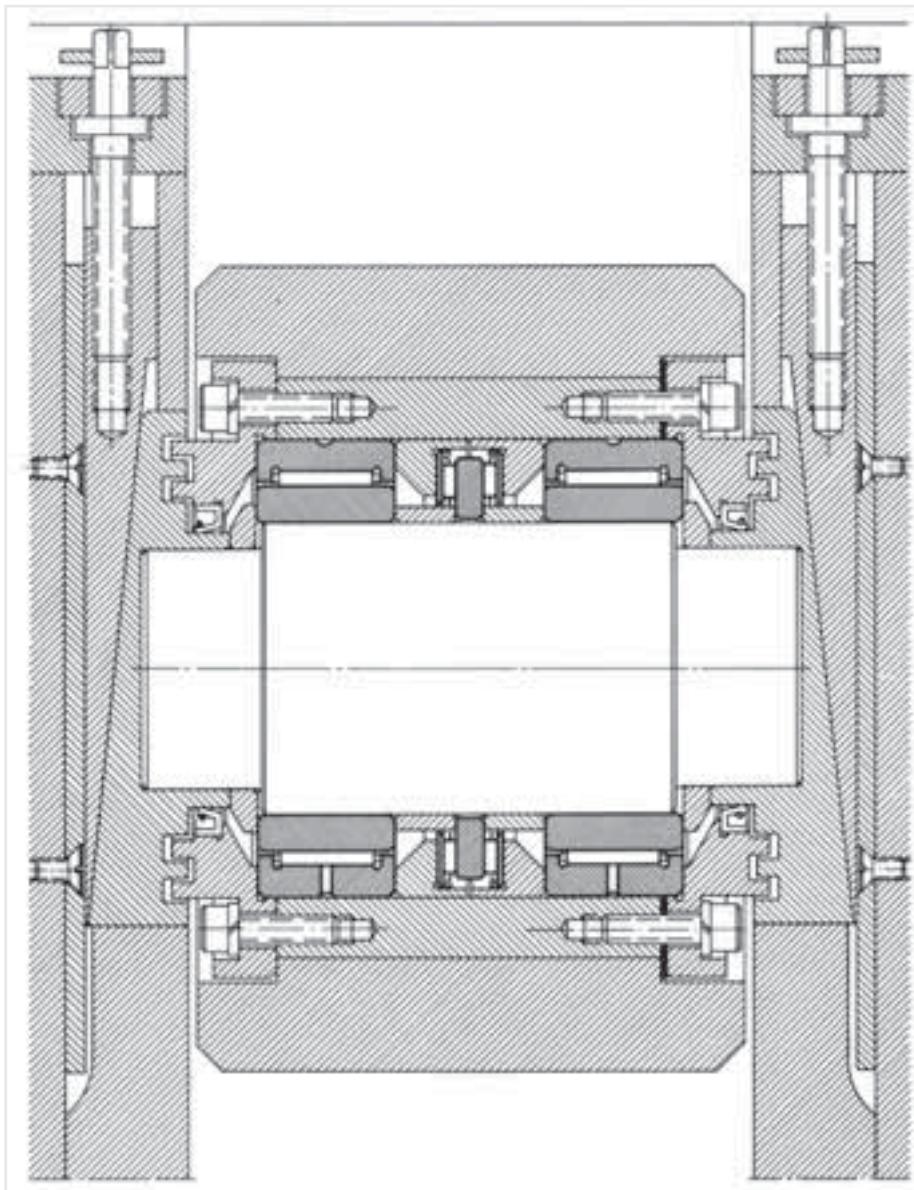

This example shows the use, on a hardened shaft, of type HK caged needle bushes, whose small radial thickness is particularly suitable for this type of application. The

outer bearing of the output shaft is supported by a HK sealed, caged needle bush. Axial drilling loads are carried by a needle thrust bearing type AX.

# Applications

## ROLLING MILL FOLLOWER

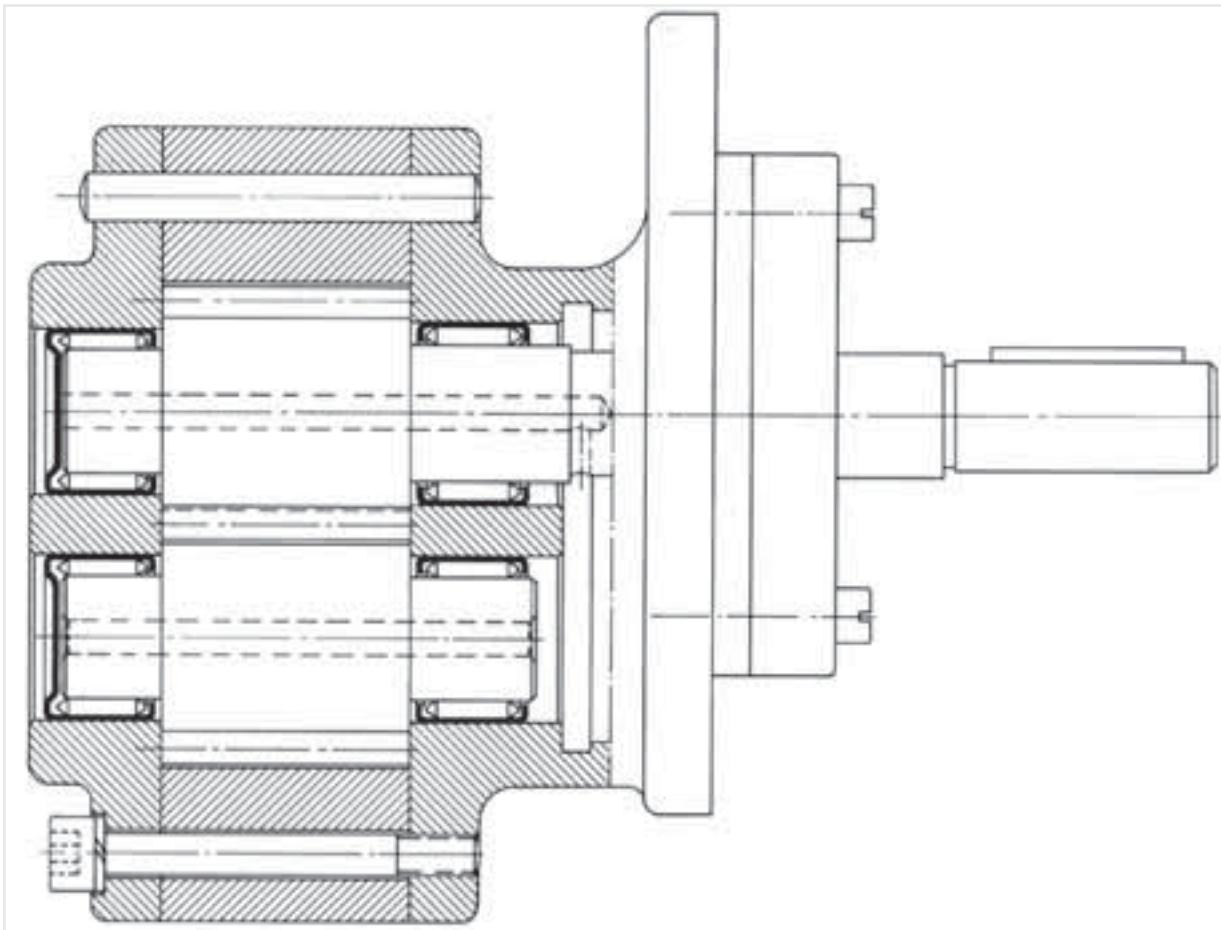

This roller guides hot rolled steel products whose temperature is around 100°C. A cooling spray limits the temperature of the roller to 50°C. Two NA 3 080 full complement bearing support the radial load which may be as high as 28 000 daN at a speed of 100 r.p.m.

Axial location of the rollers is by two AX needle thrust bearings of 90 mm bore, mounted either side of a CPR intermediate plate. Lip seals and grease filled labyrinth effectively prevent the ingress of coolant into the bearing

# Appliations

## GEAR PUMP

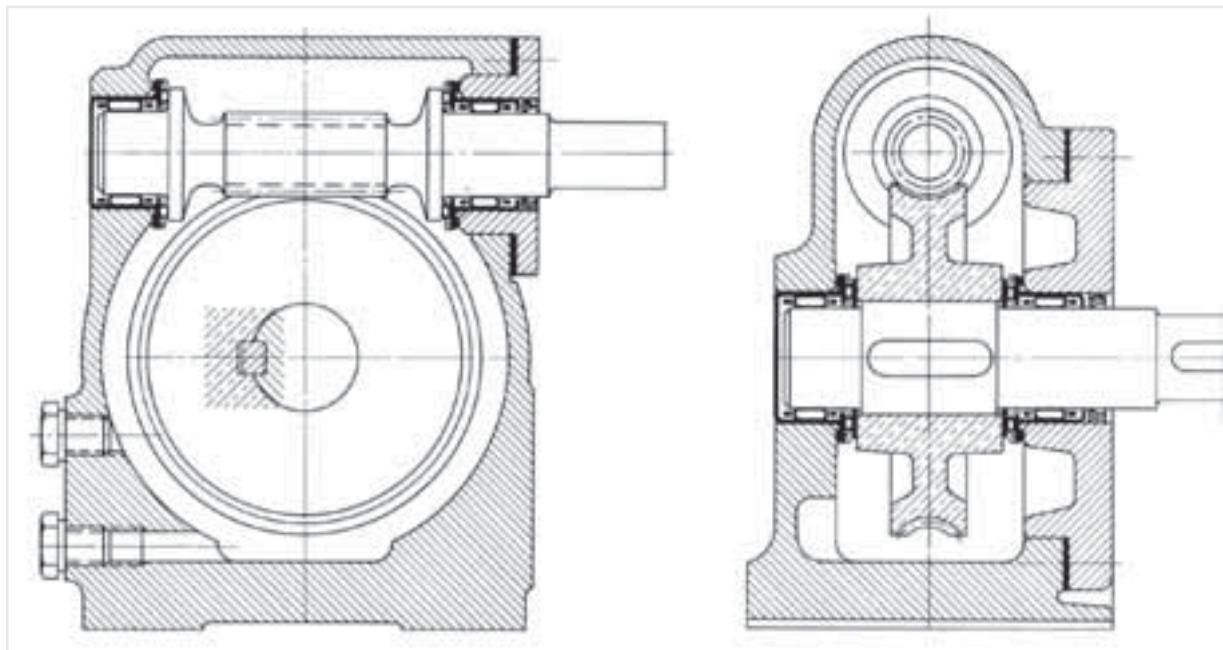

The operating conditions of this gear pump allow the use of DL and DLF full complement needle bushes bearings on the pinion journals. The DLF closed end

needle bushes ensure the sealing of the bores in the bottom plate. The trunnions, acting as raceways under the needles, are hardened to 58 HRC.

# Appliations

## WORM AND WHEEL SPEED REDUCER

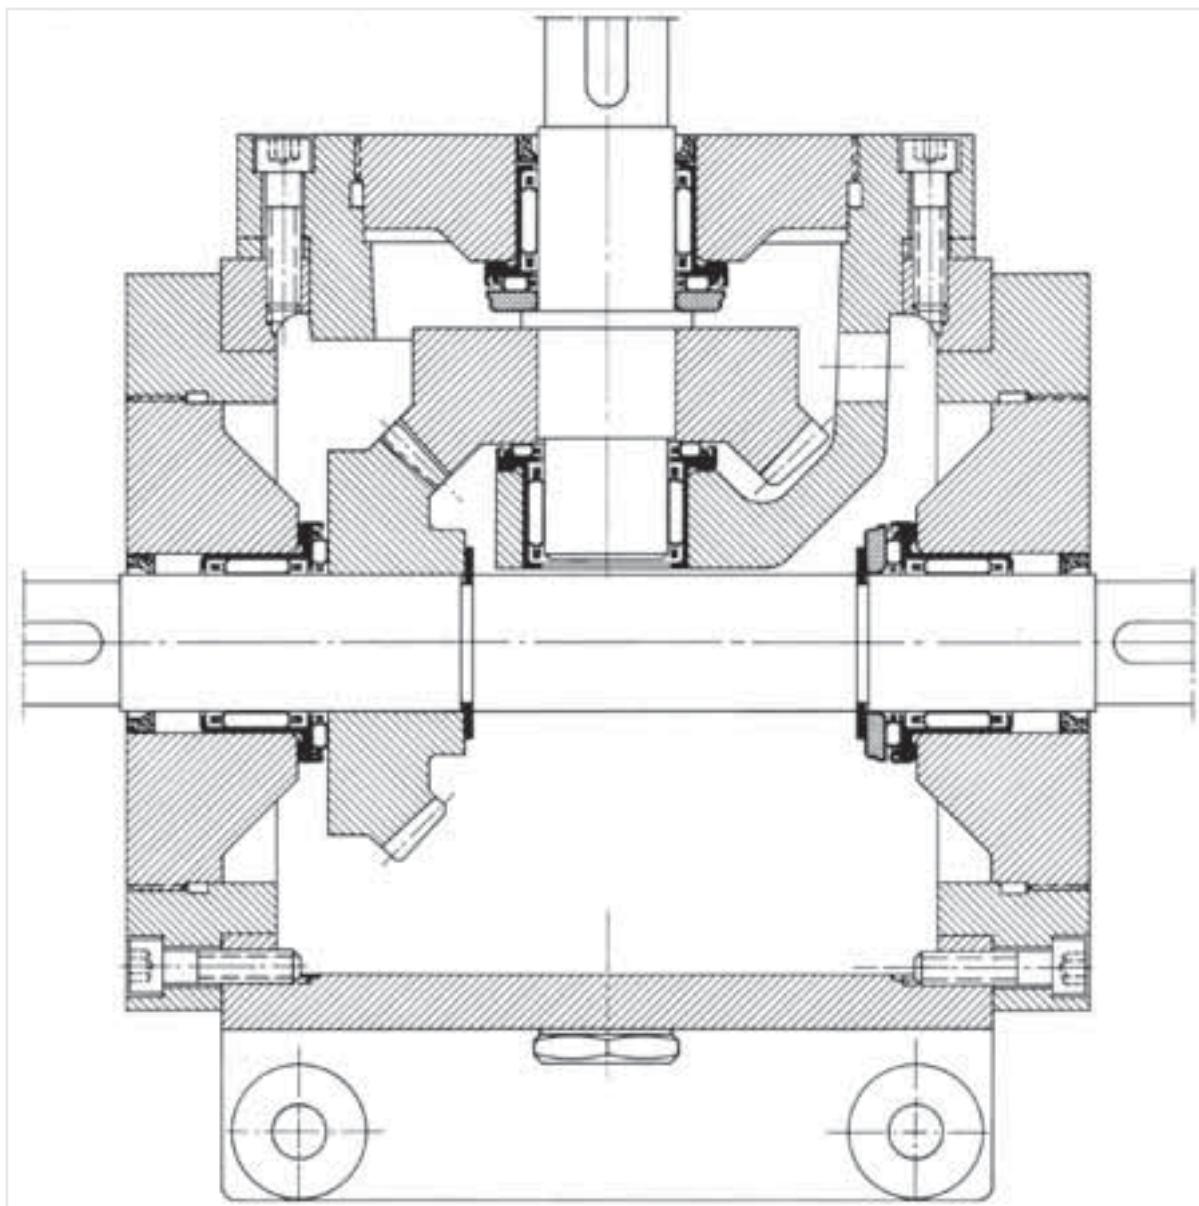

The minimal space requirement of the RAX 700 combined bearings has led to the conception of an extremely compact speed reducer with outside dimensions only slightly greater than the size of the gears. As well as achieving economy in the casting, this arrangement also allows minimal bearing span, thereby affording greater rigidity and resistance to possible deflection of the worm.

The input and output shafts are sealed by type DH sealing rings of the same radial dimensions as the corresponding bearings and the opposite ends of the same shaft by means of RAXF 700 closed end combined bearings. The shaft journals serving as bearing raceways are hardened to 58 HRC.

# Appliations

## RIGHT-ANGLE GEAR BOX

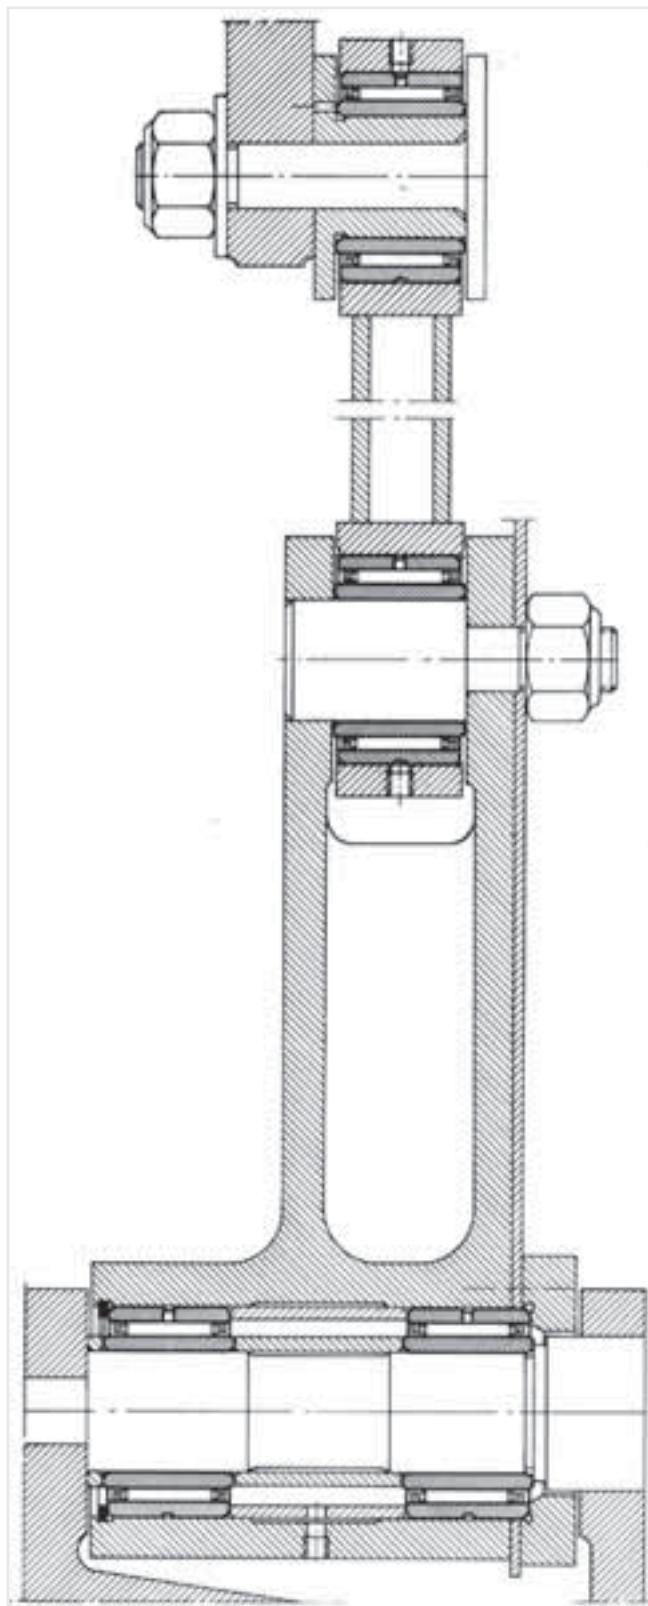

The driving shaft runs in two combined bearings types RAX 718 and RAX 720 with separate thrust plates. The driven shaft is mounted on two RAX 720 combined bearings of which one only has a separate thrust plate. The shaft journals and gear faces serving as bearing raceways are hardened to 58 HRC.

The sealing of all shafts is ensured by type DH 20 26 sealing rings.

# Appliations

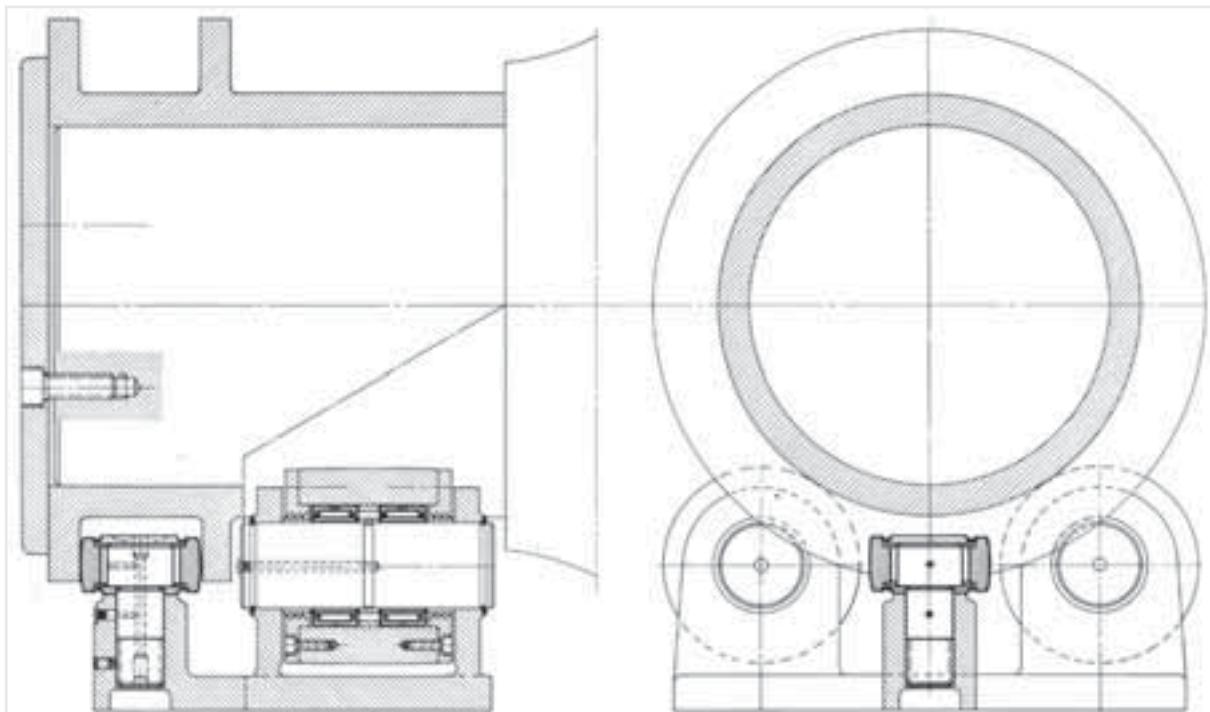

## "RAPIER" WEAVING MACHINE

On this type of weaving machine, the shuttles are replaced by "spears" or "rapiers" whose function is to project the weft thread through the warp threads to produce larger widths of cloth. The fore and aft operation of these "rapiers" is by means of a system of connecting rods whose arms are fitted with NA 22 030 full complement needle bearings (with inner races) which fully cater for the shock loadings occasioned by reversals of directions, either rotationally or under oscillating movement.

# Applications

## DRUM SUPPORT ROLLERS

These rollers are each fitted with two NK 42/20 caged needle bearings with inner rings. A GC52EE sealed cam follower with stud mounted vertically between the flanges of the sleeve, ensures lateral location of the cylinder in both directions.

This arrangement offers the following advantages:

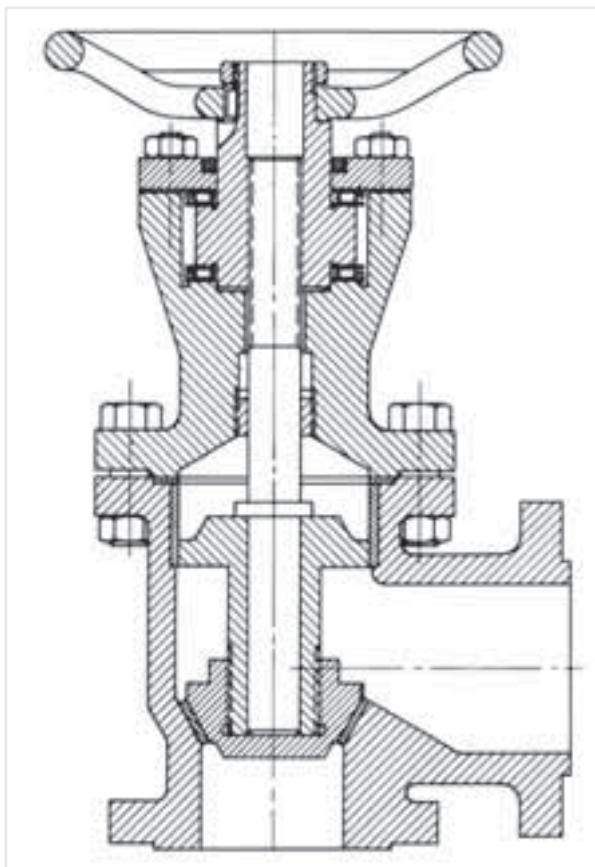

- The bearings are determined by the load to be carried rather than by the diameter of the trunnion. It is clearly preferable to sue four small bearings, rather than one of unnecessarily large diameter.

- When the drum is heated internally, only a small amount of heat is transferred to the bearings via the outside diameter and the bearings do not have to have specially increased play to allow for expansion of the inner rings, as would be the case with a large bearing mounted on the trunnion.

- Finally the coefficient of friction is much reduced and less power is required to turn the cylinder.

# Appliations

## HAND OPERATED VALVE

Threaded spindle support mounted between two needle thrust bearings, i.e. AX 45 65 (with matching thrust races) ensures low frictional characteristics and easy manual operation.

# RADIAL NEEDLE ROLLER AND CAGE ASSEMBLIES

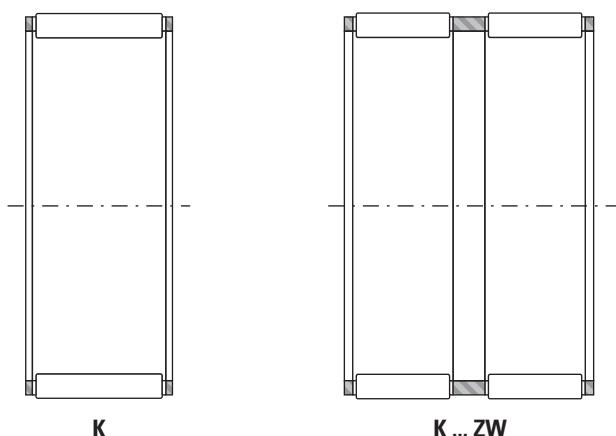

NADELLA

# Technical features

## Radial needle rollers and cage assemblies

### TYPES OF RADIAL NEEDLE ROLLER AND CAGE ASSEMBLIES

### SUFFIXES

<b>TN</b>	molded cage of reinforced engineered polymer
<b>ZW</b>	double-row
<b>TNZW</b>	molded cage of reinforced engineered polymer - double-row
<b>H</b>	hardened steel cage
<b>F</b>	machined cage
<b>FH</b>	machined cage, case hardened
<b>FV</b>	machined cage, hardened and tempered

Radial needle roller and cage assemblies have a steel cage that provides both inward and outward retention for the needle rollers. The designs provide maximum cage strength consistent with the inherent high load-ratings of needle roller bearings.

Accurate guidance of the needle rollers by the cage bars allows for operation at high speeds. Needle roller and cage assemblies have either one or two rows of needle rollers.

Also listed are needle roller and cage assemblies using molded, one-piece glass-reinforced engineered polymer cages (suffix **TN**). These operate well at temperatures up to 120° C over extended periods. However, care should be exercised when these assemblies are lubricated with oils containing additives as service life may be reduced if the operating temperature exceeds 100° C. At such high temperatures oil can deteriorate with time and it is suggested that oil change intervals are observed.

Needle rollers with relieved ends used in these assemblies are made of high-carbon chrome steel, through-hardened, ground and lapped to close tolerances for diameter and roundness.

### Reference standards are:

- **ISO 3030** - needle roller bearings - radial needle roller and cage assemblies - boundary dimensions and tolerances.
- **DIN 5405 Section 1** - rolling bearings - needle roller bearings - radial needle roller and cage assemblies.
- **ANSI/ABMA 18.1** - needle roller bearings - radial, metric design.

### DIMENSIONAL ACCURACY

#### Needle roller groups

Radial needle roller and cage assemblies are supplied with needle roller complements subdivided into groups. The groups are decided by Nadella if not differently decided during the order and with Grade G2 specified in **ISO 3096** standard (see needle rollers, page 195).

The needle roller and cage assemblies of one shipment usually contain needle rollers with group limits of between 0 ... to -2, and -5 ... -7 µm. For needle roller and cage assemblies with needle rollers of different group limits contact Technical Service Nadella.

# Technical features

## Radial needle rollers and cage assemblies

### MOUNTING DIMENSIONS

#### Design of raceways

Radial needle roller and cage assemblies use the housing bore as the outer raceway and the shaft as the inner raceway. To realize full bearing load rating and life, the housing bore and the shaft raceways must have the correct geometric and metallurgical characteristics.

The housing should be of sufficient cross section to maintain adequate roundness and running clearance under load. Additional design details for housings and shafts used as outer and inner raceways can be found in the "MOUNTING" section of this catalogue. The only limit to precision of the radial clearance of a mounted assembly is the capability of the user to hold close tolerances on the inner and outer raceways. The suggested shaft tolerances are based on housing bore tolerance G6 and apply to metric series radial needle roller and cage assemblies with needle rollers of group limits between 0.000 and -0.007.

#### Suggested shaft tolerances for housing bores machined to G6

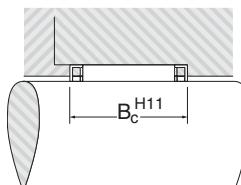

Nominal shaft diameter in mm	$\leq 80$	$> 80$
Radial clearance	Shaft tolerance	
Smaller than normal	j5	h5
Normal	h5	g5
Larger than normal	g6	f6

#### Axial guidance requirements

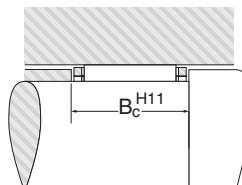

Radial needle roller and cage assembly must be axially guided by shoulders or other suitable means. The end guiding surfaces should be hardened to minimize wear and must provide sufficient axial clearance to prevent end-locking of the assembly.

Length tolerance H11 is suggested on dimension BC. If end guidance is provided by a housing shoulder at one end and by a shaft shoulder at the other end, the shaft must be axially positioned to prevent end-locking of needle roller and cage assembly.

The housing and shaft shoulder heights should be 70 percent to 90 percent of the needle roller diameter to provide proper axial guidance.

Guidance in the housing

Guidance in the shaft

#### Mounting in sets

Radial needle roller and cage assemblies that are mounted side by side must have needle rollers of the same group limits to ensure uniform load distribution.

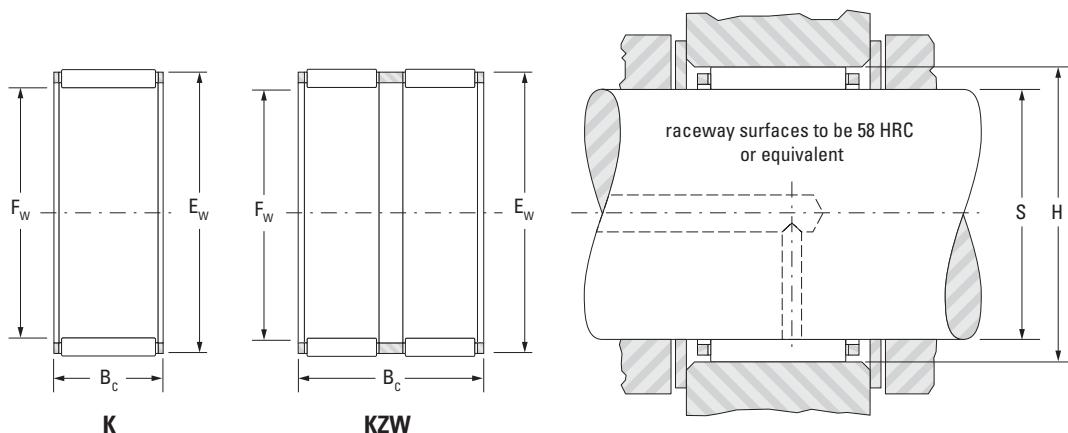

#### LUBRICATION

Oil is the preferred lubricant for most applications. In critical applications involving high speeds, ample oil flow must be provided. Where assemblies are subjected to high centrifugal forces – such as in epicyclic gearing, or inertia forces, as in the small end of a connecting rod – the contact pressure between the cage and the raceway guiding surface becomes critical. The allowable contact pressure depends on a combination of the induced force and the relative velocity between the cage and raceway and the rate of lubricant flow. Consult the Nadella Technical Service when cages will be subjected to high induced forces.

#### SPECIAL DESIGNS

Radial needle roller and cage assemblies made to special dimensions or configurations – such as those which are split to assemble around a one-piece crankshaft – can be made available on special order. Special coated or plated cages to enhance life, under conditions of marginal lubrication and high induced forces, also can be made available.

## Needle Bushes

Needle bushes consist of a thin, heat treated outer ring formed from accurately controlled sheet steel encasing a set of needles. Bushes may have a full complement of needles retained in the outer ring by their ends or by grease; others have the needles retained in a cage which is prevented from moving laterally in the outer ring.

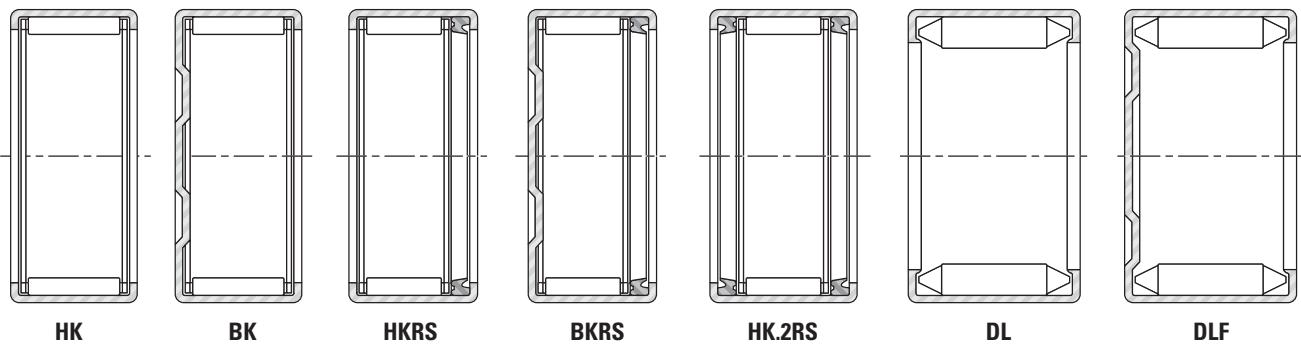

These bearings which occupy very little radial space are particularly economical to use and possess a high load capacity, relative to their size. They should be selected in preference to other bearings when conditions of mounting and operation permit.

When needle bushes are used without an inner ring and the needles rotate on a shaft of suitable hardness, they occupy minimum space and therefore provide a very satisfactory solution.

Maximum load capacity is obtained with a shaft hardness under the needles of at least 58 HRC. A lower hardness is acceptable if loads and required life permit. Hardened inner rings can be supplied for most Nadella needle bushes. They remove the necessity to harden the shaft and enable the bearings to accept full load capacity.

All needle bushes are normally supplied unlubricated (except where a special grease has been requested). However, they are coated with a thin film of grease to prevent corrosion.

### TYPES OF NEEDLE BUSHES

Suffixes	
AS1	lubricating hole
RS	seal on one side
.2RS	seal on each side

# Technical features

## Needle Bushes

### CONSTRUCTION

The outer ring, in the form of a cup, is accurately drawn and no subsequent machining is performed. Needle bushes of series **HK** and **DL** have open ends. The **HK** series also are available with one seal, **HKRS**, and with two seals, **HK.2RS**. The stamped lip of a needle bush of series **HKRS** is at the seal end.

Needle bushes of series **BK** and **DLF** are closed at one end. They are used for shaft-end mounting. The open end is typically not sealed.

Needle bushes may be made available on request with a lubricating hole, indicated by suffix **AS1**.

The one-piece steel cage used in most cases of needle bushes is designed to provide rigidity and minimize wear. This cage design separates the needle roller guiding and retention functions.

### Caged needle bushes incorporating seals

Caged needle bushes type **HK...RS** and **HK...2RS** have a seal incorporated on the inside of the face marked with the bearing part number. To this face should be applied the force necessary for installation or two seals version **2RS**. Thus, after fitting, the seal will normally be situated towards the outside of the bearing to prevent loss of lubricant and the entry of dirt, etc. (fig. 4).

If sealing is also necessary on the opposite side, a separate sealing ring type **DH** (see page 189), of the same internal and external diameters as the needle bush may be used or, if available, a needle bush **HK...2RS**. The bearing seal which is made of synthetic rubber permits operation up to 120°C (minimum running temperature -20°C).

The shaft to be introduced into the needle bush on assembly must be chamfered at its end or at its shoulder (fig. 4). When carrying out this operation the surface passing through the seal must be greased, in order to avoid damages.

### INNER RINGS

Inner rings for needle bushes are normally supplied without oil hole and have a cylindrical needle track. In those infrequent cases where lubrication is provided through the shaft, inner rings can be supplied on request with an oil hole (series **JR...JS1**).

Inner rings series **JRZ...JS1** are without installation chamfers, allowing for maximum possible raceway contact. See section "Inner rings" on pag. 68 for further details.

### LOAD RATING FACTORS

#### Dynamic loads

Needle bushes can accommodate only radial loads.

P= The maximum dynamic radial load that may be applied to a needle bush based on the dynamic load rating C, given in the bearing tables. This load should be  $\leq C/3$ .

#### Static loads

$$f_0 = \frac{C_0}{P_0}$$

$f_0$  = static load safety factor

$C_0$  = basic static load rating (kN)

$P_0$  = maximum applied static load (kN)

To ensure satisfactory operation of needle bushes, under all types of conditions, the static load safety factor  $f_0$  should be  $\geq 3$ .

# Technical features

## Needle Bushes

### INSTALLATION

For needle bushes one must accept that the thin outer ring is interference fitted to the housing bore and will correspond closely to the shape of the housing.

A housing with localised imperfections and thickness variations may cause deformation of the bush, which is detrimental to smooth operation. Best results are obtained with a geometrically uniform shape and even load distribution.

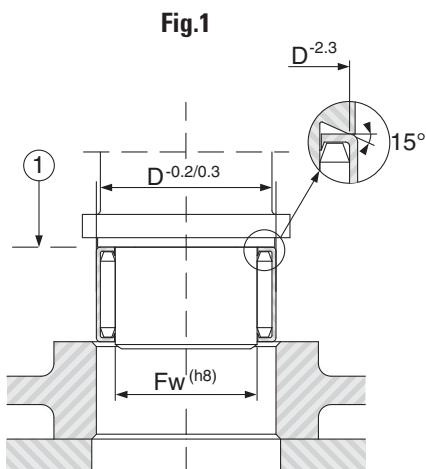

A mounting with interference of needle bushes in the housing obviates any lateral sealing device. The side of the bush not marked must remain moved away from any shoulder, seal, cover, spacer or edge of another bush. If for machining required there is a housing with shoulders, the latter must be sufficiently moved away from the bush to avoid deforming the edge during mounting.

The force required to insert the needle bush must be applied without shock to the side marked with the bearing part number.

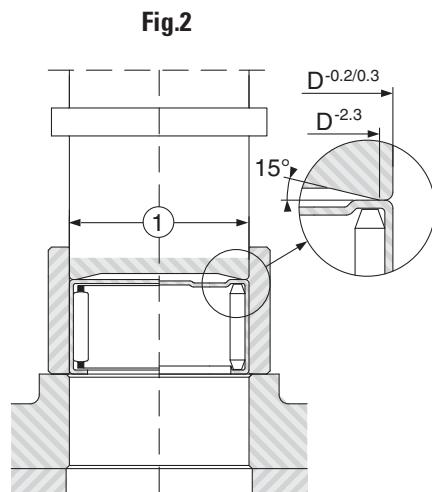

Thus it is advisable to use a small press fitted with a suitable mandrel to apply uniform force to the bush centred in the housing (fig. 1).

The axial movement of the mandrel should be limited by a shoulder coming against the face of the housing. Bushes having one closed end should preferably have the open end presented to the housing bore (fig. 2).

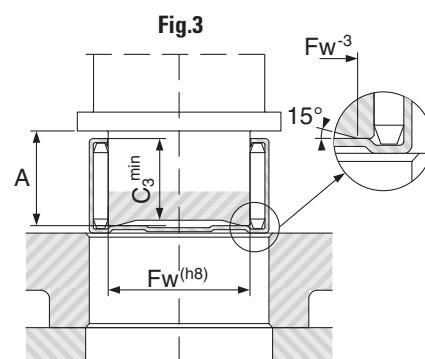

If this is not possible, the force may be applied to the inside face of the closed end in the case of bushes type **DLF** (fig. 3) (this must not be done in the case of bushes type **BK**).

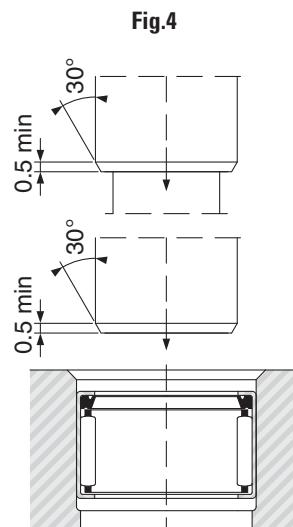

(1) Marked face

(1) Bore of ring D + 0.3 mm

A min = C3 min + 1 mm

## Needle Bushes

### RADIAL PLAY

The fit of a bush in its housing determines to a large extent the dimension under the needles after fitting and consequently the radial play during operation. The recommended shaft and housing tolerances give a radial play the limits of which are suitable for most normal applications. To obtain a closer clearance, it is possible to match the shaft diameters with the diameters under the needles of the bushes after the latter have been fitted into their housings.

The possible differences in the rigidity of housings and the variations of clamping force resulting from the tolerance build up do not permit one to establish a range of dimensions under the needles for every application. The radial play limits should also take into account the tolerance of the shaft used directly as a raceway or the outer diameter of the inner ring after it has been fitted on to the shaft.

It is suggested that when inner rings are used with needle bushes, they should be mounted with a loose transition fit on the shaft using g6 (g5) shaft diameter tolerance. The inner ring should be end-clamped against a shoulder. If a tight transition fit must be used [shaft diameter tolerance h6 (h5)] to keep the inner ring from rotating relative to the shaft, the inner ring outer diameter, as mounted, must not exceed the raceway diameter required by the needle bush for the particular application. In case the outer diameter of the inner ring, when mounted on the shaft, exceeds the required raceway diameter for the matching needle bush, it should be ground to proper diameter while mounted on the shaft.

### SHAFT TOLERANCES

Types of bush	Operating conditions	Shaft tolerance, needle bushes without inner ring (recommended internal radial play)	Shaft tolerance, needle bushes with inner ring (recommended internal radial play)	Housing tolerance (recommended internal radial play)
<b>HK, BK, HKRS, HK.2RS</b>	One piece heavy section steel or cast iron housing	h5 (h6)	h6 (h5)	N6 (N7)
<b>DL, DLF</b>	One piece heavy section steel or cast iron housing	h5 (h6)	h6 (h5)	H6 (H7)
<b>HK, BK, HKRS, HK.2RS</b>	Housing material of low rigidity (Non-ferrous metal (1) or thin casings in steel)	h5 (h6)	h6 (h5)	R6 (R7)
<b>DL, DLF</b>	Housing material of low rigidity (Non-ferrous metal (1) or thin casings in steel)	h5 (h6)	h6 (h5)	M6 (M7)
<b>HK, BK, HKRS, HK.2RS</b>	Outer ring rotation (one piece heavy section steel or cast iron housing)	f5 (f6)	g6 (g5)	R6 (R7)
<b>DL, DLF</b>	Outer ring rotation (one piece heavy section steel or cast iron housing)	f5 (f6)	g6 (g5)	M6 (M7)
<b>HK, BK, HKRS, HK.2RS</b>	Oscillating motion	j5 (j6)	h6 (h5)	(2)
<b>DL, DLF</b>	Oscillating motion	j5 (j6)	h6 (h5)	(2)

(1) If a housing of non-ferrous metal reaches temperatures considerably higher (or lower) than 20°C, account should be taken of the difference in expansion (or contraction) of the bush and suitable adjustments to the fits should be made.

The cylindrical tolerance defined as the difference in radii of two coaxial cylinders (Standard ISO 1101) must normally be less than a quarter of the machining tolerance on the defined diameter. However, for precision applications or high speeds, it is recommended that the cylindrical tolerance is reduced to one eighth of the machining tolerance.

(2) The tolerance depends on the shape of the housing.

# Technical features

## Needle Bushes

### INSPECTION OF NEEDLE BUSHES

Although the bush is accurately drawn from strip steel, because of its fairly thin section, it may go out-of-round during heat treatment. When the bearing is pressed into a true round housing, or ring gage of correct size and wall thickness, it becomes round and is sized properly.

**For this reason, it is incorrect to inspect an unmounted drawn cup bearing by measuring the outer diameter.**

The correct method for inspecting the needle bush size is to:

1. Press the needle bush into a ring gage of proper size.
2. Plug the needle bush bore with the appropriate "GO" and "NO GO" gages, or measure it with a tapered arbor (lathe mandrel).

The "GO" gage size is the minimum needle roller complement bore diameter. The "NO GO" gage size is larger than the maximum needle roller complement bore diameter.

# Internal rings for needle bushes

When it is impractical to meet the shaft raceway design requirements (hardness, surface finish, case depth, etc.) outlined in the engineering section of this catalogue, standard inner rings may be used.

Inner rings are made of rolling bearing steel and after hardening, their bores, raceways and end surfaces are ground. Inner rings may be used to provide inner raceway surfaces for radial needle roller and cage assemblies, needle roller bearings and needle bushes. The extended inner rings are suitable for use with bearings containing lip contact seals and for applications in which axial movement may be present.

## CONSTRUCTION

Inner rings are available in four basic designs and differ only by the chamfers at the ends of the raceway surfaces, the lubricant access holes and the raceway profile. Inner rings of series **JR** have chamfers to assist in bearing installation but are without lubricating holes. Inner rings of series **JR.JS1** have bearing installation chamfers and lubricating holes (bore diameters 5 to 50 mm). Inner rings of series **JRZ.JS1** are without installation chamfers, allowing for maximum possible raceway contact.

## DIMENSIONAL ACCURACY

The tolerances of size, form, and runout for inner rings meet the requirements of ISO normal tolerance class for radial bearings (see tables at the end of the catalogue). Most inner rings are produced with outside diameter raceway tolerance in accordance with h5 which, in most cases, is suitable for combining the needle roller bearings to give the normal clearance class, and for use with needle bushes.

Other raceway tolerances may also be found on inner rings for combining with needle roller bearings to give one of the clearance requirement.

## MOUNTING OF INNER RINGS

Inner rings may be mounted on the shaft with either a loose transition fit or an interference fit.

These fits used in conjunction with the proper fit of the bearing outer ring, will provide the correct operating clearances for most applications.

Regardless of the fit of the inner ring on the shaft, the inner ring should be axially located by shaft shoulders or other positive means. The shaft shoulder diameter adjacent to the inner ring must not exceed the inner ring outside diameter.

When inner rings are to be used with the needle roller bearings, appropriate shaft tolerances should be selected from table 3 on page 94 in the needle bearing section. When inner rings are to be used with needle bushes the suggested shaft tolerances are given in the "Radial play" paragraph on page 57 of the "Needle bushes" section of this catalogue.

## SEALING RINGS

Sealing rings series **DH**, tabulated on pages 191 to 193 are of a small cross section suitable for use with needle bushes. They provide a cost effective and compact construction in applications using grease lubrication.

## CONSTRUCTION

Sealing rings series **DH** comprise of a steel angle casing on the outside and a molded nitrile rubber sealing element containing the sealing lip.

These seals have an operating temperature range of -20°C to + 120°C.

## MOUNTING OF LIP CONTACT SEALS

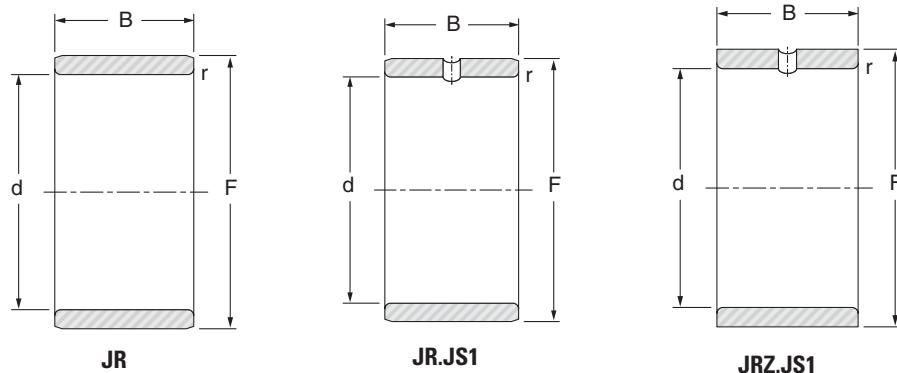

It is generally sufficient to press the seal into its predetermined position. Axial locating devices are not required for the seals in normal circumstances.

The shaft surface on which the seal is to run must be hardened and preferably plunge ground to a smooth finish, free from burrs, nicks or scratches which may damage the sealing lip.

The end of the shaft should be chamfered or rounded to prevent lip damage and to ease installation. It is also recommended to apply a coating of a suitable lubricant on the shaft before mounting the seal.

# DRAWN CUP ROLLER CLUTCHES

---

NADELLA

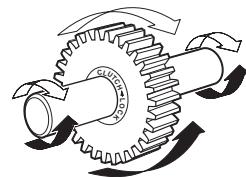

# Technical features

## Drawn cup roller clutches

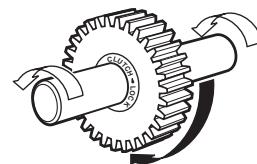

Drawn cup roller clutch transmits torque between shaft and housing in one direction and allows free overrun in the opposite direction. When transmitting torque, either the shaft or the housing can be the input member. Applications are generally described as indexing, backstopping or overrunning.

**Lock function**  
Shaft drives gear clockwise (white arrows) or gear can drive shaft counter clockwise (black arrows)

**Overrun function**  
Shaft overruns in gear counterclockwise (white arrows) or gear overruns on shaft clockwise (black arrow)

### IDENTIFICATION

The basic types of clutches and clutch and bearing assemblies are listed below:

<b>FCS, FC-K</b>	Regular clutch, single roller per stainless steel spring.
<b>FC</b>	Regular clutch, multi-roller per stainless steel spring.
<b>FCB</b>	Regular clutch and bearing assembly, multi-roller per stainless steel spring.
<b>FCL-K</b>	Light series clutch, single roller per stainless steel spring.
<b>FCBL-K, FCBN-K</b>	Light series clutch and bearing assembly. Single roller per stainless steel spring.

### TYPES OF CLUTCHES AND CLUTCH AND BEARING ASSEMBLIES

Drawn cup roller clutch **type FC** with stainless steel springs

## Drawn cup roller clutches

### CONSTRUCTION

In many respects, construction is similar to that of needle bushes. The well-established design utilizes the same low-profile radial section as needle bushes. The precisely formed interior ramps provide surfaces against which the needle rollers wedge. These positively lock the clutch with the shaft when rotated in the proper direction. These ramps, formed during the operation of drawing the cup, are case hardened for wear resistance.

Two designs of precision molded clutch cages are employed. Clutch and clutch and bearing assembly types – **FC, FC-K, FCS, FCL-K, FCB, FCBN-K, FCBL-K** – use a glass fiber, reinforced nylon cage, equipped with inserted stainless steel leaf springs. The stainless steel springs permit higher rates of clutch engagement and achieve greater spring life. The nylon cage permits operation at higher temperatures.

Types **FCB, FCBL-K, FCBN-K**, clutch and bearing assemblies have cages, for retention and guidance of the needle rollers in the bearings, located on both sides of the clutch unit.

Clutch and bearing assembly

Types **FC, FC-K, FCS, FCL-K** are of clutch-only configurations for use with external radial support (usually two needle bushes). Separate bearings position the shaft and housing concentrically and carry the radial load during overrun.

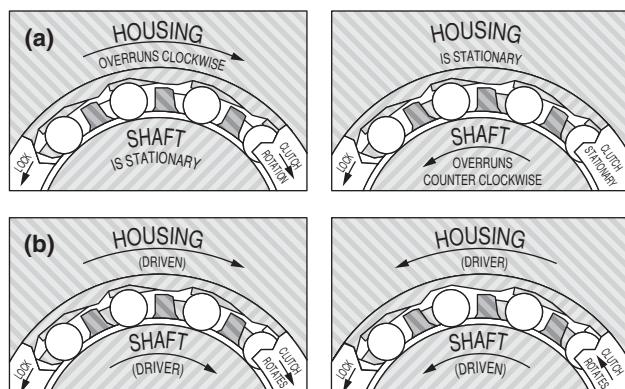

Clutch only

### OPERATION

Operation is in two modes: the **overrun mode** and the **lock mode**. Operational mode is controlled by the direction of the clutch or shaft rotation with respect to the locking ramps.

In the **overrun mode**, shown in the drawings below (a), the relative rotation between the housed clutch and the shaft causes the rollers to move away from their locking position against the locking ramps in the needle bush. The housing and the clutch are then free to overrun in one direction, or the shaft is free to overrun in the other direction.

In the **lock mode**, shown in the drawings below (b), the relative rotation between the housed clutch and the shaft is opposite to that in the overrun mode. The rollers, assisted by the leaf-type springs, become wedged between the locking ramps and the shaft to transmit torque between the two members. Either the member housing the clutch drives the shaft in one direction, or the shaft can drive the clutch and its housing member in the other direction.

Clearance between the rollers and cup ramps is exaggerated in these drawings

## Drawn cup roller clutches

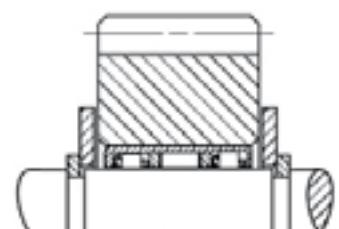

### APPLICATIONS

Clutches and clutch and bearing assemblies are successfully applied in a wide range of commercial products where indexing, backstopping and overrunning operations must be performed reliably. The sketches on these pages illustrate some of the many possible uses. When applying the clutch-only unit, separate bearings on each side of the clutch are required to position the shaft concentrically with the housing, and to carry the radial loads during overrun. Needle bushes, with the same radial section as the clutch, should be used in the through-bored housings for simplicity and economy. Two clutches can be used side by side for greater torque capacity.

Where the radial loads are light, the clutch and bearing assembly can be used without additional support bearings. This reduces the overall assembly width, the number of stocked and ordered parts and assembly costs, as well.

Clutch and bearing arrangement  
for heavy loads

Clutch and bearing assembly  
for light loads

Drawn cup roller clutches are manufactured to commercial hardware standards and are used extensively in appliances, business machines, industrial and recreation equipment and a wide range of other applications.

In any application where our clutch may be considered, it will be part of a system in which the operating conditions and the clutch mounting will affect its function.

Before any clutch selection is made, it is important that the following catalog section be carefully studied to understand the effects of these factors.

Consideration should be given to operating conditions such as:

- Magnitude of externally applied torque, as well as inertial torque.
- Magnitude of applied radial loads during overrunning.
- Potential for vibration or axial shaft movement within the clutch during engagement.
- Engagement rate, as it pertains to the selection of stainless steel or plastic leaf springs.
- Oil lubricant supply during high overrunning speeds.
- External and internal environmental temperatures that can affect clutch performance.
- Lubricant selection effect on clutch engagement.
- Indexing inaccuracies resulting from backlash (lost motion).

Consideration should be given to the shaft and housing design requirements such as:

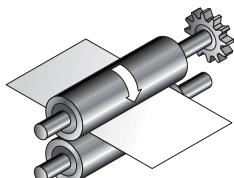

- Shaft hardness and strength particularly when approaching torque rating limits.
- Shaft roundness, taper and surface finish necessary to ensure sufficient fatigue life and torque-carrying ability.
- Housing strength (hardness and cross section) to support the applied torque loads.
- Housing roundness, taper and surface finish necessary to ensure uniform torque and load distribution.

A test program under all expected operating conditions should be carried out before putting a new application into production.

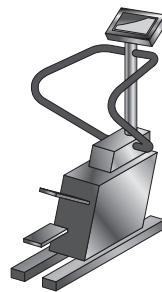

Customer engineers are constantly working with and testing new applications, and their experience can be of great help to the designer considering the use of a drawn cup roller clutch.

## Drawn cup roller clutches

### HOUSING DESIGN

Drawn cup clutches and clutch and bearing assemblies are mounted with a simple press fit in their housings. Through-bored and chamfered housings are preferred. A 30 degree angle is suggested and care should be taken to round the edge where the chamfer meets the housing bore. A sharp edge at this location can greatly increase installation forces. Provisions for axial location, such as shoulders or snap rings, are not required. The case hardened cups must be properly supported. Steel housings are preferred and must be used for applications involving high-torque loads to prevent radial expansion of the clutch cups. The suggested minimum housing outer diameters in the tables of dimensions are for steel. The housing bore should be round within one-half of the diameter tolerance.

The taper within the length of the outer ring should not exceed 0.013 mm. The surface finish of the housing bore should not exceed 1.6  $\mu\text{m}$  Ra.

The torque ratings, given in the clutch tables, are based on a steel housing of a large section. When other housing material must be used (such as aluminium, powdered metal and plastics), the torque rating of the clutch will be reduced. Such housings may be satisfactory for lightly torqued applications. But, the Technical Service should be consulted for appropriate housing and shaft suggestions. Otherwise, an insufficient press fit and use of a lower strength housing material can result in more internal clearance and reduced performance of the clutch.

When using non-steel housings, thorough testing of the design is suggested. Adhesive compounds can be used to prevent creeping rotation of the clutch in plastic housings with low friction properties. Adhesives will not provide proper support in oversized metal housings. When using adhesives, care must be taken to keep the adhesive out of the clutches and bearings.

### SHAFT DESIGN

The clutch or clutch and bearing assembly operates directly on the shaft whose specifications of dimension, hardness and surface finish are well within standard manufacturing limits.

Either case-hardening or through-hardening grades of good bearing quality steel are satisfactory for raceways. Steels modified for free machining, such as those high in sulfur content and particularly those containing lead, are seldom satisfactory for raceways.

For long fatigue life, the shaft raceway must have a hardness equivalent to 58 HRC minimum and must be ground to the suggested diameter shown in the tables of dimensions. It may be through hardened, or it may be case hardened with an effective case depth of 0.40 mm. Effective case depth is defined as the distance from the surface inward to the equivalent of 50 HRC hardness level after grinding.

Taper within the length of the raceway should not exceed 0.008 mm, or one-half the diameter tolerance – whichever is smaller. The radial deviation from true circular form of the raceway should not exceed 0.0025 mm for diameters up to and including 25 mm. For raceways greater than 25 mm, the allowable radial deviation should not exceed 0.0025 mm multiplied by a factor of the raceway diameter divided by 25. Surface finish on the raceway should not exceed 0.4  $\mu\text{m}$  Ra. Deviations will reduce the load capacity and fatigue life of the shaft.

### INSTALLATION

Simplicity of installation promotes additional cost savings.

The drawn cup roller clutch or the clutch and bearing assembly must be pressed into its housing. Procedures are virtually identical with those for installing needle bushes. The unit is pressed into the bore of a gear or pulley hub or housing of the proper size. No shoulders, splines, keys, screws or snap rings are required.

Installation procedures are summarized in the following sketches on page 84.

Use an arbor press or hydraulic ram press (fig. 1) to exert steady pressure. Never use a hammer, or other tool requiring pounding to drive the clutch into its housing.

# Technical features

## Drawn cup roller clutches

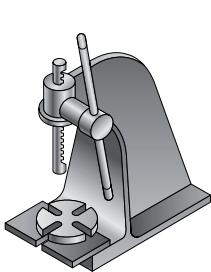

fig. 1

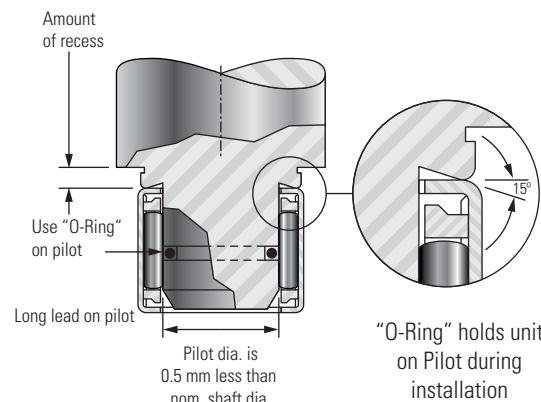

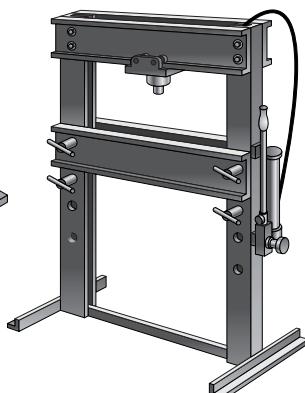

fig. 2

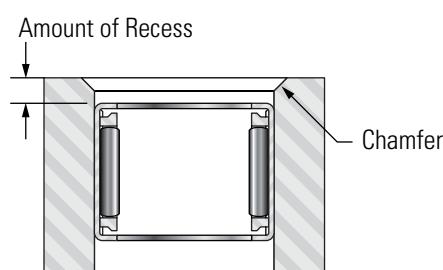

fig. 3

**IMPORTANT:** The mounted clutch engages when the housing is rotated relative to the shaft in the direction of the arrow and lock marking (LOCK) stamped on the cup. Make sure that the unit is oriented properly before pressing it into its housing.

When assembling the shaft, it should be rotated in the overrun direction during insertion. The end of the shaft should have a large chamfer or rounding (fig. 4).

Use an installation tool as shown in fig. 2. If the clutch is straddled by needle roller bearings, press units into position – in proper sequence – and preferably leave a small clearance between units.

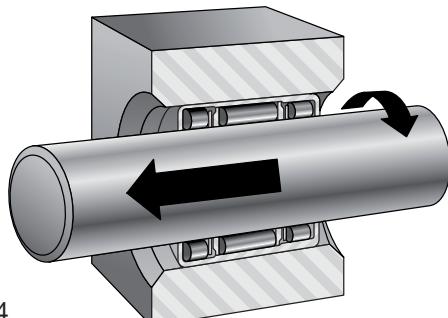

fig. 4

### APPLIED LOADS

The clutch-only unit is designed to transmit purely torque loads. Applied torque should not exceed the catalog ratings, which are based on the compressive strength of well-aligned clutch components.

Bearings on either side of the clutch are to assure concentricity between the shaft and the housing to support radial loads during clutch overrun. Integral clutch and bearing assemblies are available for this purpose, especially where the radial loads are light. The total maximum dynamic radial load that may be shared by the two needle roller and cage radial bearing assemblies should not be greater than C/3.

In determining the total torque load on a clutch, it is essential to consider the torque, due to inertial forces developed in the mechanism, in addition to the externally applied torque. The larger the clutch, and the greater the mass of the mechanism controlled by it, the more important this consideration becomes.

Clutch lockup depends on friction. For this reason, applications involving severe vibrations or axial motion of the shaft within the clutch are to be avoided. Applications where overhanging or overturning loads occur should incorporate bearings that will maintain alignment between the shaft and the clutch housing.

Consult Technical Service for suggestions.

# Technical features

## Drawn cup roller clutches

### LUBRICATION

Oil is the preferred lubricant; it minimizes wear and heat generation. For those applications where oil is not practical, clutches are packed with a soft grease containing mineral oil. Thick grease will retard roller engagement and can cause individual rollers to slip, possibly overloading any engaged rollers.

### TEMPERATURE

Temperature extremes can cause clutch malfunctions and failure. The molded plastic cage with integral springs holds its necessary resiliency and strength when the operating temperature within the clutch is kept below 90° C. The clutch with reinforced nylon cage and separate steel springs operates well at temperatures up to 120° C continuously and to 150° C intermittently. Excessive thickening of the lubricant at low temperatures may prevent some, or all, of the rollers from engaging. New applications should be tested under expected operating conditions to determine whether or not temperature problems exist.

### BACKLASH

Backlash, or lost motion, prior to engagement is minimal. The variation in backlash from one cycle to another is extremely low. Grease lubrication, or improper fit (housing bore and shaft diameter), may increase backlash. Angular displacement between the shaft and housing increases as an applied torque load is increased.

### RATE OF ENGAGEMENT

Clutch lockup depends upon static friction. Axial motion between shaft and clutch rollers prevents lockup. Clutches with integral springs engage satisfactorily at cyclic rates up to 200 engagements per minute. Intermittent operation at higher rates has been successful. The steel spring type clutches have proven dependability at rates up to 6000 or 7000 engagements per minute. Even higher cyclic rates may be practical. Because grease may impair engagement at high cyclic rates, a light oil should be used.

### OVERRUN LIMIT SPEED RATING

Exact limiting speed ratings are not easily predictable. The value for each clutch given in the bearing tables is not absolute but serves as a guide for the designer. Oil lubrication is absolutely necessary for high speed operations. Consult Technical Service when overrunning speeds are high.

### INSPECTION

Although the outer cup of the clutch is accurately drawn from strip steel, it can go slightly out of round during heat treat. When the assembly is pressed into a ring gage, or properly prepared housing of correct size and wall thickness, it becomes round and properly sized. Direct measurement of the outer diameter of a drawn cup assembly **is an incorrect procedure**.

The proper inspection procedure is as follows:

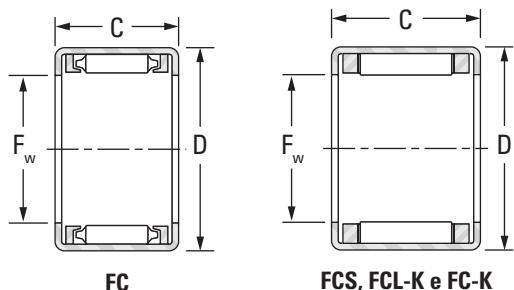

1. Press the assembly into a ring gage of the proper size, as given in the tables.
2. Gage the bore with the specified plug gages of the proper size, as given in the tables of dimensions.
  - a. The locking plug is rotated to ensure lockup when the clutch is operated on a low-limit shaft and is mounted in a high-limit housing, strong enough to properly size the clutch.
  - b. The overrun plug is rotated to ensure free overrunning when the clutch is operated on a high-limit shaft and is mounted in a low-limit housing.
  - c. The "go" plug and "no go" plug ensure proper size of the bearings in the clutch and bearing assemblies.

Gage sizes are listed in the tables of dimensions. Plug gage sizes reflect adjustment for the loose and tight conditions resulting from high or low housings or shafts.

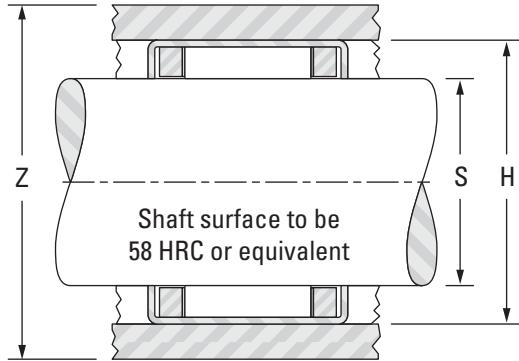

# Drawn cup roller clutches

Shaft raceway and housing bore diameters that are necessary for proper mounting and operation are listed on the opposite page. Types **FC**, **FC-K**, **FCS** and **FCL-K** clutches have stainless steel springs inserted in molded cage to position rollers for lockup.

# Drawn cup roller clutches

Proper inspection requires installation of the clutch in a ring gauge and then checking the bore with the appropriate plug gauges. Please read the section on "INSPECTION" on page 85.

When applying these clutches, it is important that separate bearings be used adjacent to the clutches to carry radial loads and assure concentricity between the shaft and housing. For full details on "INSTALLATION" see page 83.

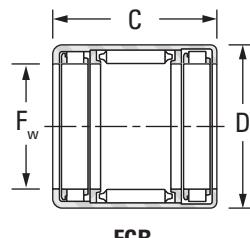

**The mounted clutch engages when the housing is rotated relative to the shaft in the direction of the arrow marking (← LOCK) stamped on the cup.**

# BEARINGS WITH CAGE - GUIDED NEEDLES

---

NADELLA

# Technical features

## Bearings with cage - guided needles

Caged needle bearings possess an outer ring made from through-hardened bearing steel. The cage guides the needles and retains them in the outer ring.

The bearings may be used without an inner ring if the shaft journal serving as a raceway is of sufficient hardness and has the correct surface finish. To ensure that the full load capacity of these bearings is achieved, a hardness of 58-64 HRC is required. A lower hardness will entail a reduction in the load capacities (both dynamic and static) as shown in the table of dimensions (see Technical Section).

### CONSTRUCTION

The basic constructions of needle roller bearings are:

- with integral end flanges on the one-piece, channel-shaped outer rings ( $F_w \geq 12$  mm)
- with inserted-end washers to provide axial retention of the needle roller and cage assemblies ( $F_w \leq 10$  mm).

### Needle roller bearings with integral flanges

The needle roller bearing has a one-piece, channel-shaped outer ring of bearing-quality steel heat treated to yield maximum load rating.

The integral end flanges provide axial location for the needle rollers. The bores of the end flanges serve as piloting surfaces for the cage.

A steel cage provides inward retention for the needle rollers, and the design assures roller stability and minimizes friction between the cage and the needle rollers. The cage has maximum strength consistent with the inherent high-load ratings of needle roller bearings. The outer ring has a lubricating groove and a lubricating hole for more convenient lubrication of the bearing. However, the smaller bearings of series **NKJ** ( $d \leq 7$  mm) and **NK** ( $F_w \leq 10$  mm) do not have a lubricating groove or a lubricating hole.

### Reference standards are:

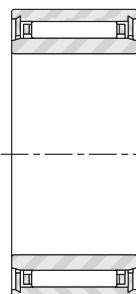

- ISO 1206 - Needle roller bearings - Light and medium series - Dimensions and tolerances.

# Technical features

## Bearings with cage - guided needles

### Needle roller bearings with inner rings

When it is impractical to finish the shaft to meet the desired raceway design requirements, an inner ring may be used. Standard needle roller bearings are available with inner rings to form complete bearings. Bearings furnished with inner rings meet the quality requirements in accordance with ISO standards.

- For inner- and outer-ring tolerances, the bearings follow the normal tolerance class in **ISO Standard 492** covering radial bearings. Bearings to more precise tolerance classes, P6 and P5, may be obtained upon request (see tables at the end of the catalogue).
- These bearings may be obtained with radial internal clearance in accordance with **ISO Standard 5753**, also specified for cylindrical roller bearings. Mostly, they follow the normal (C0) radial clearance group, although bearings to clearance groups C2, C3 and C4 may be made available on request (see tables at the end of the catalogue).
- Inner ring and outer ring chamfer dimensions meet the requirements of **ISO Standard 582**.

### Needle roller bearings without inner rings

Whenever the shaft can be used as the inner raceway, needle roller bearings without inner rings provide advantages of economy and close control of radial internal clearance in operation. Tolerance class F6 is the normal specification for the needle roller complement bore diameter of an unmouted bearing, as shown in Table 1.

**Table 1 - Caged needle roller complement bore diameter for bearings without inner rings**

F <sub>w</sub> mm		ΔF <sub>w</sub> min μm	
>	≤	low	high
	6	+10	+18

10	18	+16	+27
18	30	+20	+33
30	50	+25	+41
50	80	+30	+49
80	120	+36	+58
120	180	+43	+68
180	250	+50	+79
250	315	+56	+88
315	400	+62	+98

### BEARING MOUNTING

#### General requirements

In general the mounting of needle roller bearings with or without inner rings, of normal precision, requires the shaft seat or raceway to be machined to quality IT5 or IT6. The housing bore should meet quality IT6 or IT7. Other quality requirements for shafts and housings are given on page 13.

#### Mounting dimensions

It is suggested that needle roller bearings are mounted in their housings with a clearance fit, if the load is stationary relative to the housing, or with a tight transition fit, if the load rotates relative to the housing. Table 2 lists the suggested tolerances for the housing bore and the shaft raceway for bearings without inner rings. Table 3 lists the suggested shaft tolerances for the above two mounting conditions when the bearings are used with inner rings.

Other mounting dimensions may be required for special operating conditions such as:

1. Extremely heavy radial loads.
2. Shock loads.
3. Temperature gradient across bearing.
4. Housing material with heat expansion coefficient different than that of the bearing.
5. Oscillating motion applications.

**Table 2 - Mounting tolerances for bearings without inner ring**

Rotation conditions	Nominal housing bore diameter D mm	ISO tolerance zone for housing	Nominal shaft diameter F mm	ISO tolerance zone for shaft
Load stationary relative to housing	All diameters	H7 (J7)	All diameters	h6
General work with larger clearance	All diameters	K7	All diameters	g6
Load rotates relative to housing	All diameters	N7	All diameters	f6

**NOTE:** Care should be taken that the selected bearing internal clearance is appropriate for the operating conditions. Details of shaft and housing quality requirements are given on pages 13 and 14.

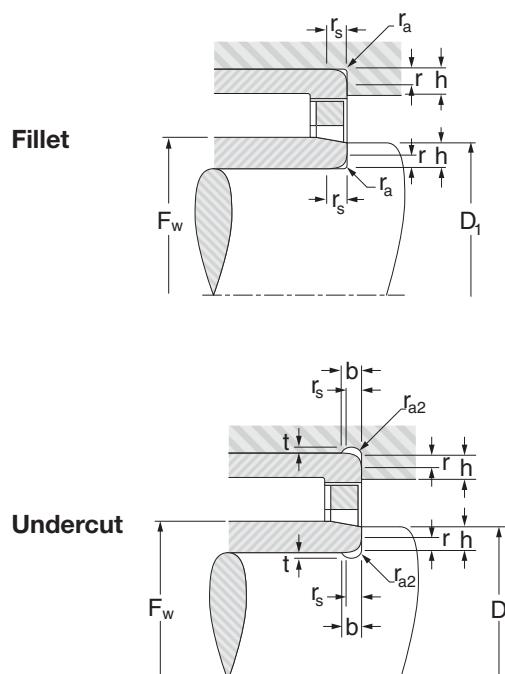

# Technical features

## Bearings with cage - guided needles

**Table 3 - Shaft tolerances for bearings with inner**

Rotation conditions	Nominal shaft diameter $d_1$ mm		ISO tolerance zone for shaft
Load rotates relative to housing	All diameters		g6
Load stationary relative to housing	>	$\leq$	
		40	k6
	40	100	m6
	100	140	m6
	140		n6

**NOTE:** Care should be taken that the selected bearing internal clearance is appropriate for the operating conditions. Details of shaft and housing quality requirements are given on pages 13 and 14.

**Table 4 - Fillets, undercuts, and shoulder heights**

$r_s$ min mm	$r_{as}$ max	t	$r_{a2}$ min	b	h min
0,15	0,15				0,6
0,3	0,3				1
0,6	0,6				2
1	1	0,2	1,3	2	2,5
1,1	1	0,3	2	3	3,25
1,5	1,5	0,4	2	3,2	4
2	2	0,5	2,5	4	5
2,1	2,1	0,5	3	4,7	5,5
3	2,5	0,5	3,5	5,3	6

Regardless of the fit of the bearing outer ring in the housing, the outer ring should be axially located by housing shoulders or other positive means. The bearing rings should closely fit against the shaft and housing shoulders and must not contact the fillet radius.

The maximum shaft or housing fillet  $r_{a\max}$  should be no greater than the minimum bearing chamfer  $r_s\min$  as shown in Table 4.

In order to permit mounting and dismounting of the shaft, the maximum diameter  $D_{max}$ , in Table 5 must not be exceeded.  $F_w$  is shown in the bearing tables.

**Table 5 - Shoulder diameter  $D_{1\max}$**

		Dimensions in mm				
Needle roller complement bore diameter $F_w$	>		20	55	100	250
	$\leq$	20	55	100	250	
Diameter	$D_{max}$	$F_w-0,3$	$F_w-0,5$	$F_w-0,7$	$F_w-1$	$F_w-1,5$

### LOAD RATING FACTORS

#### Dynamic loads

Needle roller bearings can accommodate only radial loads.

The maximum dynamic radial load that may be applied to a needle roller bearing based on the dynamic load rating C, given in the bearing tables, should be  $\leq C/3$ .

#### Static loads

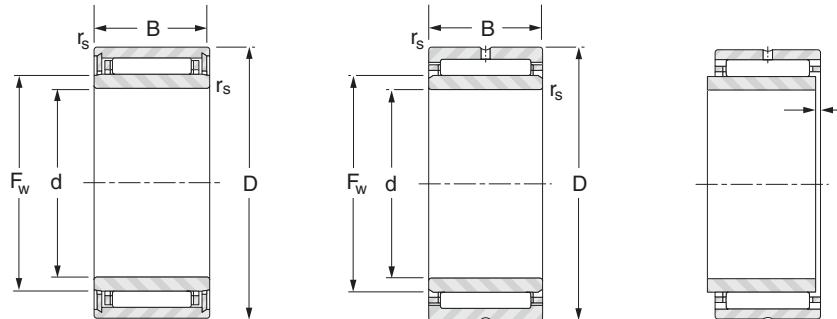

Needle roller bearings can accommodate only radial loads.

The maximum static radial load that may be applied to a needle roller bearing is based on the static load rating  $C_0$  given in the bearing tables. For calculations see the section "Technical notes" on page 11.

#### Mounting in sets

Radial needle roller bearings which are mounted side by side must or must have the same cross-section and radial internal clearance, after mounting.

# Technical features

## Full complement needle bearings

Full complement needle bearings have a through-hardened outer ring which results in high static and dynamic load capacities and an ability to withstand overloading, shocks and vibration.

They are particularly suitable for operations involving oscillating motion but may also accept high speed conditions where good alignment is necessary. This can more easily be achieved using a convex inner ring raceway (inner rings with suffix R6).

The retention of the needles in the outer ring enables the bearing to be installed easily during assembly.

The difference between the needle bearings with integral end flanges series 3000 and the others is explained in the Chapter of the Bearings with cages.

These bearings are available with or without an inner ring from 12 mm bore size. Standard complete bearings type **NA** have an inner ring with convex raceway form. If extra wide inner rings or rings with lubrication hole are required, they should be ordered separately for use with the corresponding **RNA** series.

### Reference standards are:

- **ISO 1206** - Needle roller bearings – Light and medium series – Dimensions and tolerances.

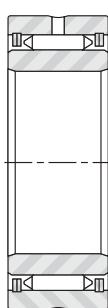

### FULL COMPLEMENT BEARINGS WITHOUT INNER RING

The shaft journal which is used directly as the inner ring raceway of the bearing should have adequate hardness and satisfactory surface finish. A hardness of 58-64 HRC will ensure full load capacity for the bearing. Lower hardness figures will entail a reduction in both static and dynamic capacities as shown in the table of dimensions (see Technical Section).

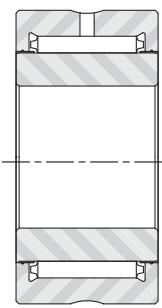

In cases of misalignment, a convex inner ring raceway can be machined directly at the shaft journal position by grinding, using a concave profile and inclining the diamond impregnated grinding wheel. A convex inner ring raceway calculated to permit misalignment of 1 in 1000 does not affect bearing load capacity. A larger convex radius is necessary for a greater degree of misalignment but this will reduce the effective bearing load capacity.

### TYPES OF BEARINGS

#### Needle roller bearings with inner rings

NA Series 1000,  
2000, 22000

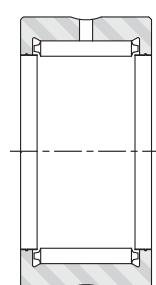

NA Series 3000

#### Needle roller bearings without inner rings

RNA Series 1000,  
2000, 22000

RNA Series 3000

## Full complement needle bearings

### INNER RINGS

Inner rings made from high quality bearing steel heat treated and through-hardened avoid any necessity for heat treatment of the shaft and enable the bearings to operate within their full load capacity.

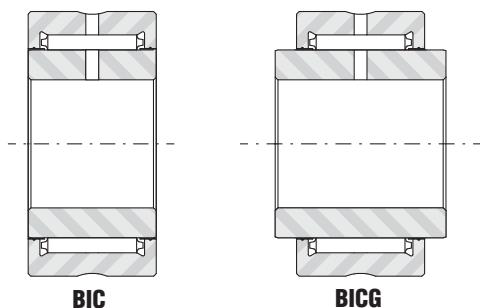

#### Inner rings with convex raceway "R6"

These inner rings without lubrication hole are of the same width as the outer ring and are supplied with series **NA** complete, types **1000, 2000, 22000** and **3000**. They can accept a misalignment of 1 in 1000 in continuous operation and up to 2 in 1000 temporarily, as in the case of sudden deflection due to overload conditions. The inner and outer rings may be displaced axially from one to the other by up to 5% of the ring width. The designation of the inner ring separated from the complete needle bearing is **BI** number **R6**. For example **BI 2020 R6**. The designation of the needle bearings complete of inner ring **BI...R6** is **NA** number. For example **NA 2035**.

#### Inner rings with cylindrical raceway

Cylindrical inner rings of the same bore as those with convex raceway may be supplied on request in the following versions:

- with oil hole permitting lubrication through the shaft (**BIC**).
- wider than corresponding outer ring (**BICG**), to enable a displacement in position of one ring relative to the other (e.g. expansion of the shaft) or lateral shaft movement. In the latter case, which can occur with or without simultaneous rotation of the shaft, please consult Nadella Technical Service.

The use of cylindrical inner rings with standard bearings type **RNA** series **1000, 2000, 22000** and **3000** requires that the housing and shaft be correctly aligned at assembly with due regard to the application under load. If it is not essential to use these inner rings, it is always preferable to use complete bearings type **NA** with convex inner rings type "**R6**", without oil hole, of the same width as the outer ring. In particular cases where lubrication is provided through the shaft, the inner ring with oil hole may be replaced by a lubrication hole at the face of the inner ring.

### RING TOLERANCES

Inner and outer rings for full complement standard needle bearings are manufactured in accordance with the tolerance class of ISO Standard 492 (class zero according to DIN 620). Closer tolerances, corresponding to classes 6, 5 and 4 may be necessary for special high precision applications (symbols P6, P5, P4). See table at the end of the catalogue.

### RADIALPLAY

#### Bearings without inner ring

The radial play of a bearing without inner ring results from the difference in diameter beneath the needles and the size of the shaft. The standard diameter beneath the needles for RNA bearings with the recommended shaft tolerances should provide suitable radial play for most normal applications.

For special applications (high precision, close fits, etc.), we can offer the diameter beneath the needles selected as follows:

- in the bottom half of the normal tolerance (**RNA ... TB**)
- in the upper half of the normal tolerance (**RNA...TC**).

Bearings without inner ring tolerance Class **TB** mounted on a shaft with k5 tolerance will have a reduced radial play suitable for certain applications.

Nominal dimension $F_w$ mm	to	Tolerance of diameter under needles		
		normal μm	Selected TB μm	Selected TC μm
above				
5	15	+20 + 40	+20 + 31	+ 29 + 40

25	30	+25 + 48	+25 + 38	+ 35 + 48
30	35	+30 + 53	+30 + 43	+ 40 + 53
35	60	+35 + 58	+35 + 48	+ 45 + 58
60	80	+45 + 73	+45 + 60	+ 58 + 73
80	115	+50 + 78	+50 + 65	+ 63 + 78
115	180	+60 + 88	+60 + 75	+ 73 + 88
180	220	+70 + 103	+70 + 88	+ 85 + 103
220	270	+80 + 113	+80 + 98	+ 95 + 113
270	350	+90 + 128	+90 + 110	+108 + 128
Examples of bearing		RNA 1020	RNA 1020 TB	RNA 1020 TC

A nominal diameter under the needles further reduced may be required for certain precision.

Should a larger clearance than normal be necessary, the shaft diameter must be controlled nearer to the nominal size than the tolerances h5 or g5 would normally provide.

# Technical features

## Full complement needle bearings

### Standard complete bearings with inner ring

Complete bearings type **NA** are offered with a radial play that is suitable for the majority of applications. They can be supplied if necessary:

- with the radial play selected from the bottom half of the normal tolerance (**NA...TB**)
- with the radial play selected from the upper half of the normal tolerance (**NA...TC**).

For bore dimensions  $d > 130$  mm, bearings **NA...TB** or **NA...TC** are supplied only on special request.

## Full complement needle bearings

### BEARING MOUNTING

#### General requirements

In general, the mounting of needle roller bearings with or without inner rings, of normal precision, requires the shaft seat or raceway to be machined to quality IT5 or IT6. The housing bore should meet quality IT6 or IT7. Other quality requirements for shaft and housings are given on page 13.

### MOUNTING DIMENSIONS

It is recommended that needle roller bearings are mounted in their housings with a clearance fit if the load is stationary relative to the housing, and with a tight transition fit if the load rotates relative to the housing.

Table 2 lists the recommended tolerances for the housing bore and the shaft raceway for bearings without inner rings. Table 3 lists the recommended shaft tolerances for the above two mounting conditions when the bearings are used with inner rings.

Other mounting dimensions may be required for special operating conditions such as:

1. Extremely heavy radial loads
2. Shock loads
3. Temperature gradient across bearing
4. Housing material with heat expansion coefficient different to that of the bearing
5. Oscillating movements

**Table 2- Mounting tolerances for bearings without inner ring**

Rotation conditions	Nominal housing bore diameter $D$ mm	ISO tolerance zone for housing	Nominal shaft diameter $F$ mm	ISO tolerance zone for shaft
Load stationary relative to housing	All diameters	J6	All diameters	h5
Load rotates relative to housing	All diameters	M6	All diameters	g5

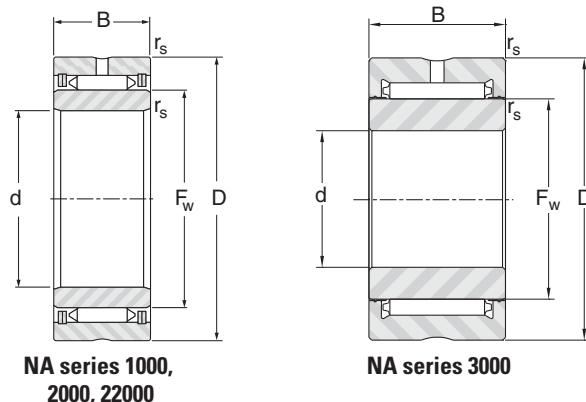

**NOTE:** Care should be taken that the selected bearing internal clearance is appropriate for the operating conditions. Details of shaft and housing quality requirements are given on pages 13 and 14.

**Table 3- Shaft tolerances for bearings with inner rings**

Rotation conditions	Nominal shaft diameter $d$ mm		ISO tolerance zone for shaft	Nominal housing bore diameter $D$ mm	ISO tolerance zone for housing
Load stationary relative to housing	All diameters		h5 (h6)	All diameters	J6

# CAM FOLLOWERS

NADELLA

# Technical features

## Cam followers

Nadella cam followers are designed to run directly on various types of surface such as cams, ramps and slideways.

In order to satisfy the operating conditions imposed on this type of bearing - heavy radial loads usually accompanied by substantial and repeated shocks, the various Nadella cam followers have these common advantages:

- heavy section outer ring for carrying load and limiting deformations that reduce the load capacity of the bearing
- convex outer ring tolerating out-of-parallelism of contact surfaces or cylindrical outer ring for reducing contact pressure
- oil holes situated under the needles enabling lubricant replenishment through the shaft
- full complement of needles or rollers providing maximum dynamic and static load capacities

Cam followers can be equipped with an eccentric stud in order to allow setting the preload during the mounting. Cam followers can be equipped with plastic seals or metallic shields for retaining lubricant.

Besides the standard products in the catalogue, Nadella manufactures several variations for specific conditions of use.

### Reference standards are:

**ISO 7063** – Needle roller bearings – Track rollers – boundary dimensions.

### TO USE AS FOLLOWERS

When the cam followers or the wheels are used for running on a rail or a cam, under the load there is a plastic deformation of the outer ring that reduces the load distribution between the rolling elements of the bearings. The tables in the following pages list two different values of the basic load of the bearing depending from the use and mounting.

- the load capacity **C** valued according to standard ISO 281 for bearings, for lifetime calculations when mounting with the cylindrical outer ring in a hole.
- the load capacity **Cw**, for lifetime calculations when mounting with the cylindrical outer ring running in contact with a cam or plain guide rail.

In addition to the load capacity of the bearing you must consider the strength of the outer ring and of the stud in the cam followers.

Dynamic limit load **Fr**: it is the load which should not be exceeded when follower is subject to repeated torques.

Static limit load **For**: it is the maximum strength limit that the follower can exceptionally support.

In case of use like a wheel the strength of the raceway must be considered. For more details, please ask to Technical Service Nadella.

# Technical features

## Cam followers

### TYPES AND OPERATING CONDITIONS

#### Full complement needle followers types GC

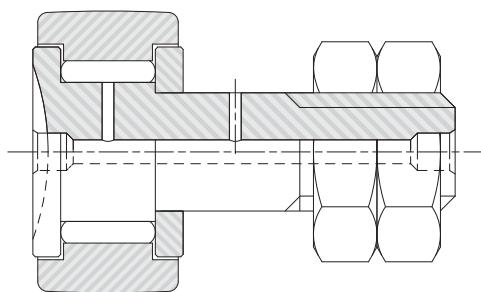

These followers are recommended under following conditions:

- low speeds
- high radial loads
- oscillating motions

Convex outer ring (**GC**) or cylindrical (**GCL**)

With eccentric stud (**GCR** or **GCRL**)

Starting from dimension 16 can be equipped with contact plastic seals (suffix **EE**) or contact metallic shields (suffix **EEM**)

#### Single-row full complement roller followers types GCU

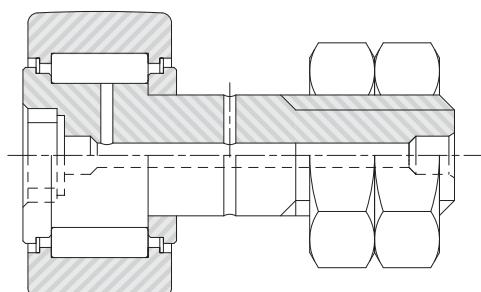

Their installation is especially recommended for:

- high speeds
- limited and intermittent axial loads
- heavy radial loads

Convex outer ring (**GCU**) or cylindrical (**GCUL**)

With eccentric stud (**GCUR** or **GCURL**)

With metallic shields (suffix **MM**)

#### Double-row full complement roller followers types NUKR.2SK

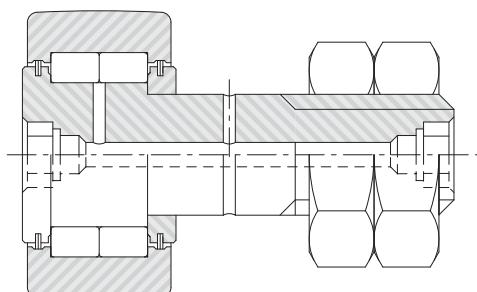

Their installation is especially recommended for:

- high speeds
- limited axial loads
- heavy radial loads

Outer ring with optimised profile with decreasing curvature from middle of the wheel

With eccentric stud (**NUKRE**)

With metallic shields (suffix **MM**)

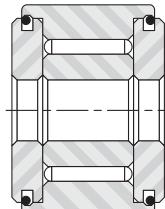

#### Small single-row full complement needle followers type FP

Their installation is especially recommended for:

- low speeds
- heavy radial loads
- oscillating motions

Convex outer ring (**FP**) or cylindrical (**FPL**)

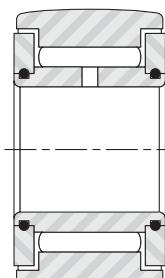

#### Single-row full complement needle followers type FG

Their installation is especially recommended for:

- low speeds
- heavy radial loads
- oscillating motions

Convex outer ring (**FG**, **FP**) or cylindrical (**FGL**, **FPL**)

Cam followers **FG** can be equipped with contact plastic seals (suffix **EE**) or contact metallic shields (suffix **EEM**)

# Technical features

## Cam followers

### Single-row full complement roller followers type FGU (heavy and light series)

Their installation is especially recommended for:

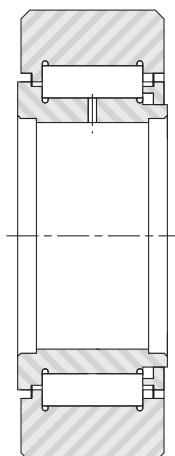

- high speeds
- limited and intermittent axial loads
- heavy radial loads

Heavy series is different from light series for the thickness of the outer ring which determinates an higher external diameter and an higher load capacity.

Convex outer ring (**FGU**) or cylindrical (**FGUL**).

Inner ring and lateral shoulders built in a single piece.

Metallic shields (suffix **MM**).

### Double-row full complement roller followers type NUTR

Their installation is especially recommended for:

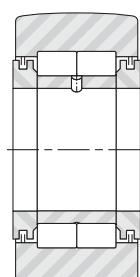

- high speeds
- limited axial loads
- heavy radial loads

Heavy series is different from light series for the thickness of the outer ring which determinates an higher external diameter and an higher load capacity.

Convex outer ring (**NUTR**) or cylindrical (**NUTR.DZ**).

Inner ring in three parts, not separable.

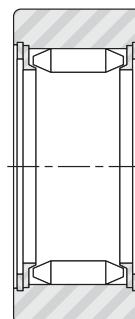

Metallic shields.

### Single-row full complement needle followers type RNA 11000

These followers useable without inner ring on a treated shaft, are available with an inner ring starting from a shaft diameter 12 mm, and their installation is especially recommended for:

- intermediate speeds
- heavy radial loads
- oscillating motions

### MISALIGNMENT TOLERANCES

Followers with a convex outer ring permit displacement in relation to the track surface up to a maximum slope like for the following table:

Cam follower type	
RNA 11 000 B6	1.5 in 1000
RNAB 11 000	15 in 1000
FG, GC, GCU	7 in 1000

### TOLERANCES ON OUTER DIAMETER

For all type of follower:

- convex outer ring h9 on dim. D
- cylindrical outer ring h7 on dim. D

Out of roundness in accordance to ISO 7063

### ADVICE ON ASSEMBLY

#### Positioning of the radial lubrication hole

In cases where the follower is subjected to high loads, shock or vibration, the lubrication hole situated under the needles should be positioned outside the loaded zone. The lubrication hole which is not visible on the cam follower with threaded stud is parallel to the screwdriver slot in the head of the stud. Where the head of the stud has a hexagonal socket, the position of the lubrication hole is indicated by the marking by the hole.

# Technical features

## Cam followers

### Lateral support of followers

For followers type **FGU** shoulders on the shaft or other parts serving to retain the follower on the faces of the inner ring should have an outer diameter not less than dimensions  $d_A$ . Where there is considerable axial load or operation is subject to vibration, this outer diameter should be equal at least to dimension  $d_A$  listed in the tables.

For followers of **FG** series shoulders on the shaft should be equal at least to dimension  $d_A$ .

For the correct mounting of followers of **NUKR** series tighten axially the bearing, the minimum diameter advised for locking is  $d_A$  listed in the tables.

### CAM FOLLOWERS GC, GCU AND NUKR SERIES

#### Tolerance on hole housing

The stud should fit easily into the hole in the mating member having a bore of tolerance H7. To ensure contact over the entire surface area of the yoke, the supporting face of the mating member should have a diameter of at least equal to dimension  $d_A$ . The locking torque applied to the nuts, as shown in the table of dimensions, is calculated to provide effective fixing of the follower.

Cam followers GC GCU NUKR series	Dimension d
Without eccentric stud	d H7
With eccentric stud	d1 H7

### CAM FOLLOWERS FG FGU RNA1000 NUTR Shaft tolerances

Cam followers NUTR FP FG FGU series	Dimension d
Load fixed in relation to the inner ring	h5 / h6
Load rotating in relation to the inner ring	k5 / j6
Load fixed in relation to the inner ring, moderate loads, high strength shaft	g6
Load fixed in relation to the inner ring, light loads, unhardened shaft, loose transition fit	f6

For RNA 11000 fitted with inner ring	Dimension d
Load fixed in relation to the inner ring	h5 / h6
Load rotating in relation to the inner ring	k5 / j6

For RNA 11000 without inner ring	Dimension Fw
Hardened and ground steel shaft	h5

The cylindrical tolerance, defined as the difference in radii of two coaxial cylinders (ISO Standard 1101), should normally be less than a quarter of the manufacturing tolerance. However, for high precision or high speed applications it is advised to restrict this tolerance to one eighth of the manufacturing tolerance.

#### LUBRICATION - OPERATING TEMPERATURE

Type **RNA 11000** followers are supplied with a coating of protective grease compatible with a lithium base grease.

As for the bearings the protective grease is not suitable for lubrication of the wheels.

All types of wheels and cam followers, with or without seals are supplied lubricated with a grease permitting operation in temperatures from -20 to +120°C. In the versions with metallic shields or in synthetic material (**EE-Teflon**) the exercise limit depends always on the lubricant. On request, these followers can be supplied with greases for high or low temperatures, or without grease (but protected against rust).

In any case, at temperatures of 150°C and above, cam followers must be specially heat treated and calculation of life should take account of reduced load capacity (consult Nadella Technical Department).

Use of a special grease for high temperatures may reduce the limiting speeds shown in the tables of dimensions.

The metallic shields ...**EEM** ...**MM** enables operation up to 200°C with a suitable lubricant.

# Technical features

## Cam followers

### ECCENTRIC STUDS

To provide radial adjustment of the outer ring toward the hole of the housing at the time of installation, track rollers are available with eccentric bushing added to the track roller stud fitted with interference. In this way the position of the bearing can be settled for a value of  $\pm k$ . The eccentric bushing closes the lubrication hole on the stud.

As a standard eccentric bushing are supplied already mounted on the stud.

### ACCESSORIES FOR FOLLOWERS

Cam followers with lubrication hole are supplied with cap and grease nipple. Insert the one or the other in the appropriate end seats in function of the side from which the lubrication will be performed.

The cap is completely inserted for all its length by pressure.

The nipple has instead a step that is not within the length of the hole for the portion that protrudes of 2.5 mm dimension h.

Cam followers of **GC** series and derived from dimension 16 up to 28 mm inclusive has a single axial hole at its top end for a grease nipple and a screw driver slot. The nipple protrudes from the edge of the head.

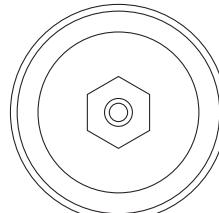

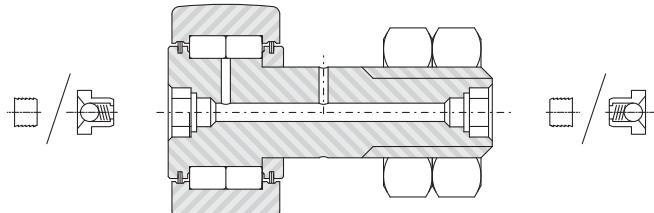

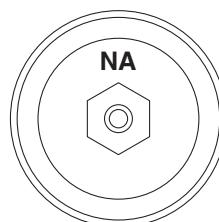

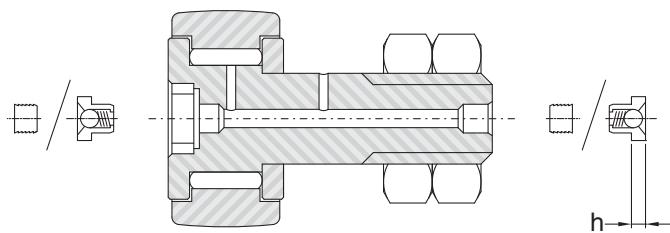

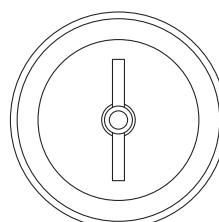

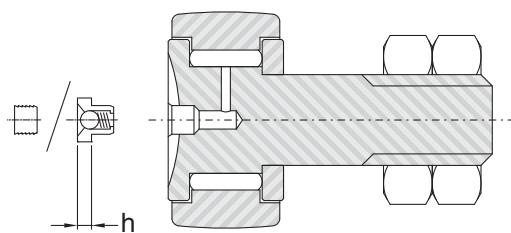

Cam followers of **GC** series, from diameter 30 mm and **GCU** series, with a hexagonal socket on head side, the nipple protrudes only if mounted on the stud side.

In cam followers **NUKR** series the nipple is always hidden in the hexagonal socket.

The radial hole in the stud, if not used, is closed by the housing of the cam follower.

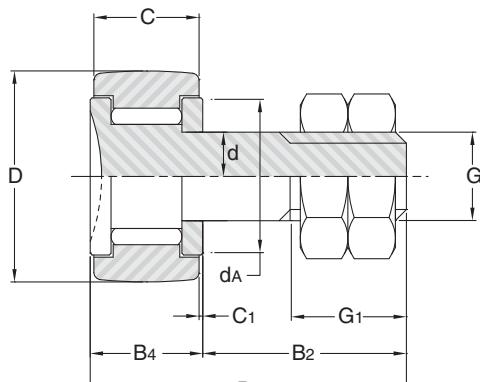

Concentric cam followers **GC GCU** and **NUKR** series are supplied with two nuts.

Eccentric cam followers **GCR GCUR NUKRE** series are supplied with eccentric bushing, one nut, one lock washer, one flat washer

## Needle thrust bearings-Roller thrust bearings

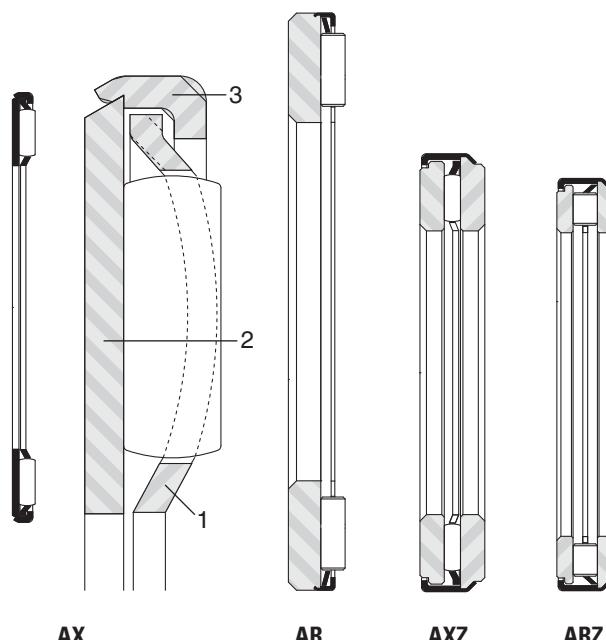

The rolling elements of a thrust bearing are retained and guided in radial pockets within the cage (1). The latter is itself retained in relation to the plate (2) by means of a steel ring (3). This assembly of parts is easy to handle and install and provides a high axial load capacity whilst occupying minimal space.

The design of Nadella thrust bearings serves to reduce to a minimum the friction between the rolling elements and the cage that guides them. Given correct installation and adequate oil lubrication, the coefficient of friction will be between 0.003 and 0.004 for needle thrust bearings and between 0.004 and 0.005 for roller thrust bearings.

This result is due principally to the design of the one-piece steel cage (1) which has a special curvature that guides the rolling elements by their ends along their centre-lines.

Thus, the loads imposed on the cage by the rollers cannot create components parallel to the axis of rotation and therefore no increase in internal friction is generated, and correct operation without wear or overheating is ensured. In addition, this special curvature gives the steel cage great rigidity and being relatively thin provides maximum space for the lubricant.

### TYPES OF THRUST BEARINGS

### THRUST PLATES

The plate incorporated in the thrust bearing is made from hardened bearing steel and forms one of the raceways for the rolling elements. The opposing raceway is generally provided by a separate thrust plate of similar design supplied by Nadella. When the thrust bearing is centred by the revolving part, the thrust plate must be centred by the stationary part and vice versa. If the revolving part and the stationary part are noticeably eccentric to each other, the thrust bearing with integral plate must without exception be centred by the revolving part (see mounting examples on pages 140 and 141). The second raceway for the rolling elements may also be formed by the face of a shoulder or an inserted ring, provided these have the correct geometrical dimensions and hardness.

### THRUST BEARINGS WITH THRUST PLATE

Thrust bearings type **AXZ** and **ARZ** have two thrust plates retained by a steel ring giving protection against the entry of dirt and metal particles whilst at the same time assisting retention of the lubricant.

### OPERATION

When the ring of rolling elements begins to rotate, it is automatically centred in relation to the shaft axis. Thus the thrust bearing does not need to be precisely centred by the incorporated plate. Hence it is possible to align the bearing (on the shaft or in the housing) allowing wide tolerances to be used and without surface hardening. This enables costs to be reduced. The same feature applies to centring of the thrust plate.

Thrust bearings with incorporated plate	Separate thrust plates	Thrust bearings with plate and thrust plate incorporated
Needle thrust bearings AX thin series AX thick series	CP thin series CP thick series	Needle thrust bearings AXZ thick series
Roller thrust bearings AR light series		Roller thrust bearings ARZ light series
AR heavy series	CPR heavy series	ARZ heavy series

Needle thrust bearings with a thin plate are of minimal thickness and are particularly economic to use. They should be considered whenever the degree of support and rotational accuracy permits.

# Technical features

## Needle thrust bearings-Roller thrust bearing

### THICKNESS AND AXIAL RUN-OUT TOLERANCES

	Internal Ø $D_{c1}$ mm	Thickness tolerance $\mu\text{m}$	Axial run-out max
Needle thrust bearings (thin)	$D_{c1} \leq 60$ $60 < D_{c1} \leq 90$ $90 < D_{c1} \leq 120$	+ 30/- 40 <sup>1)</sup> + 50/- 60 <sup>2)</sup> + 50/- 60 <sup>2)</sup>	20 <sup>1)</sup> 25 <sup>2)</sup> 30 <sup>2)</sup>
Thrust plates (thin)	$D_{c1} \leq 60$ $60 < D_{c1} \leq 90$ $90 < D_{c1} \leq 120$	+ 30/- 40 <sup>1)</sup> + 50/- 50 <sup>2)</sup> + 50/- 50 <sup>2)</sup>	20 <sup>1)</sup> 25 <sup>2)</sup> 30 <sup>2)</sup>
Needle thrust bearings (thick) Roller thrust bearings	$D_{c1} \leq 120$ $120 < D_{c1} \leq 180$ $180 < D_{c1} \leq 250$	+ 50/- 60 + 50/- 110 + 50/- 160	5* 7* 10*
Thrust plates (thick)	$D_{c1} \leq 120$ $120 < D_{c1} \leq 180$ $180 < D_{c1} \leq 250$	+ 50/- 50 + 50/- 100 + 50/- 150	5* 7* 10*

(1) Under min. load of 150 N

(2) Under min. load of 250 N

### SUPPORTING FACES

For smooth running operation of needle or roller thrust bearings, it is necessary that their supporting faces should be parallel.

For a thrust bearing with intermediate thrust plate, the permissible degree of deviation from true parallelism between the two supporting faces should be no more than 1 min. (or approx. 0.3 per 1000).

For a thrust bearing without intermediate thrust plate, the deviation must be no more than 1 min. 30 sec. (or approx. 0.45 per 1000).

Thin needle thrust bearings and thin thrust plates must be supported on a flat, rigid and continuous face throughout the area of circulation of the needles bounded by dimensions  $E_b$  and  $E_a$ .

Thick needle thrust bearings and thick thrust plates can be supported on a more restricted or discontinuous shoulder, provided that the deflection of the plate under load does not endanger the smooth operation of the thrust bearing or the axial run-out required.

Since roller thrust bearings generally run under considerable loads, their incorporated plate and thrust plate should be supported on a shoulder covering the whole area of circulation of the rollers bounded by dimensions  $E_b$  and  $E_a$ .

Where an application does not involve the use of a thrust plate, the surface forming the second raceway must:

- extend at least across the whole area of circulation of the rolling elements between dimensions  $E_b$  and  $E_a$ ;
- possess a suitable surface finish ( $\leq 0.5 \mu\text{m}$  C.L.A.) and sufficient hardness in relation to the load to be supported.

A hardness of 58-64 HRC enables thrust bearings to carry their full load capacity. Lower hardness values reduce the capacities shown in the tables of dimensions (see Technical Section).

### TOLERANCES FOR CENTRING SUPPORTS

*Centring on the shaft:* h10 on dimension  $D_{c1}$  for thrust bearings or thrust plates.

*Centring in the housing:* H10 on dimension D for thrust bearings and dimension  $d_1$  for thrust plates.

### LOAD RATINGS

#### Minimum axial load

Slippage can occur if the applied axial load is too light and the operating speed of the needle thrust bearings is high – particularly if accompanied by inadequate lubrication. For satisfactory operation, a certain minimum load must be applied to a needle thrust bearing which can be calculated from:

$$F_{a \min} = C_0 / 2200 [\text{kN}]$$

Where:

$C_0$  static load rating [kN]

$F_{a \min}$  minimum axial load [kN]

### COEFFICIENT OF FRICTION

In general, the coefficient of friction of a thrust bearing (consisting of a needle thrust bearing and thrust plate) is defined as the friction torque, divided by the product of the applied load and the bearing pitch radius. This coefficient of friction is not a constant value, but will vary considerably with load, speed and lubricant.

Generally, the coefficient of friction becomes smaller as the load is increased, and larger as the speed is increased.

It is suggested that a value of 0.008 as a conservative estimate.

### LUBRICATION

Oil is the preferred lubricant for needle thrust bearings and an ample oil flow is absolutely necessary for high speeds or for moderate speeds when the load is relatively high.

When the application must utilize grease lubrication, the needle thrust bearing should be ordered pre-greased.

When the speeds are low and rotation is not continuous, the initial charge of grease may be suitable for the life of the application.

When the speeds are moderate, the designer must provide for frequent re-greasing. Because the needle rollers tend to expel the lubricant radially outward, relubrication passages should be directed to the bore of the cage whether oil or grease is used as the lubricant.

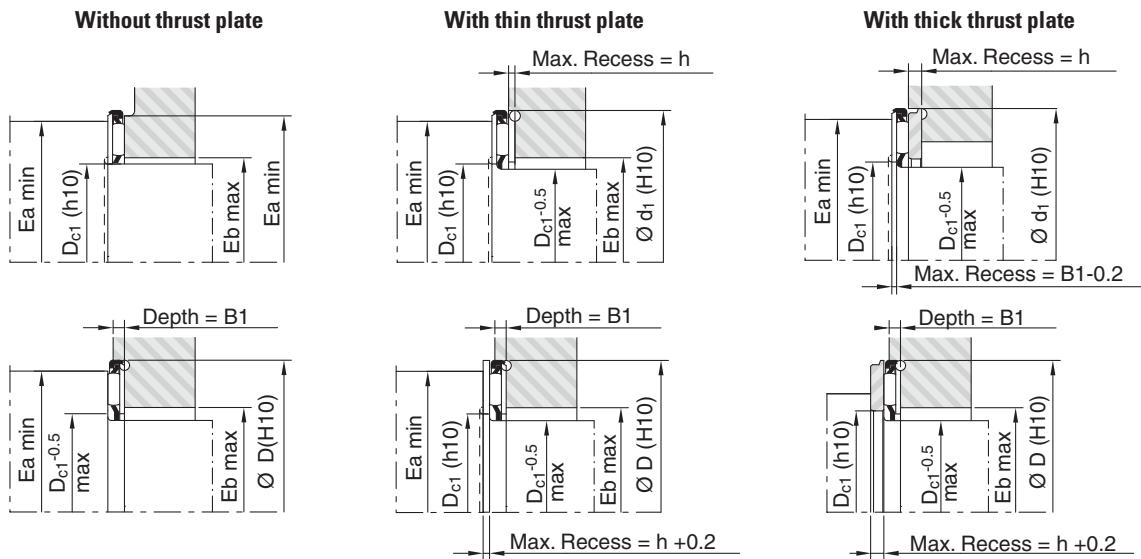

### SPECIAL DESIGNS

Needle thrust bearings and thrust plates are made to special dimensions and configurations, as well as from special materials – when quantities permit economical manufacture.

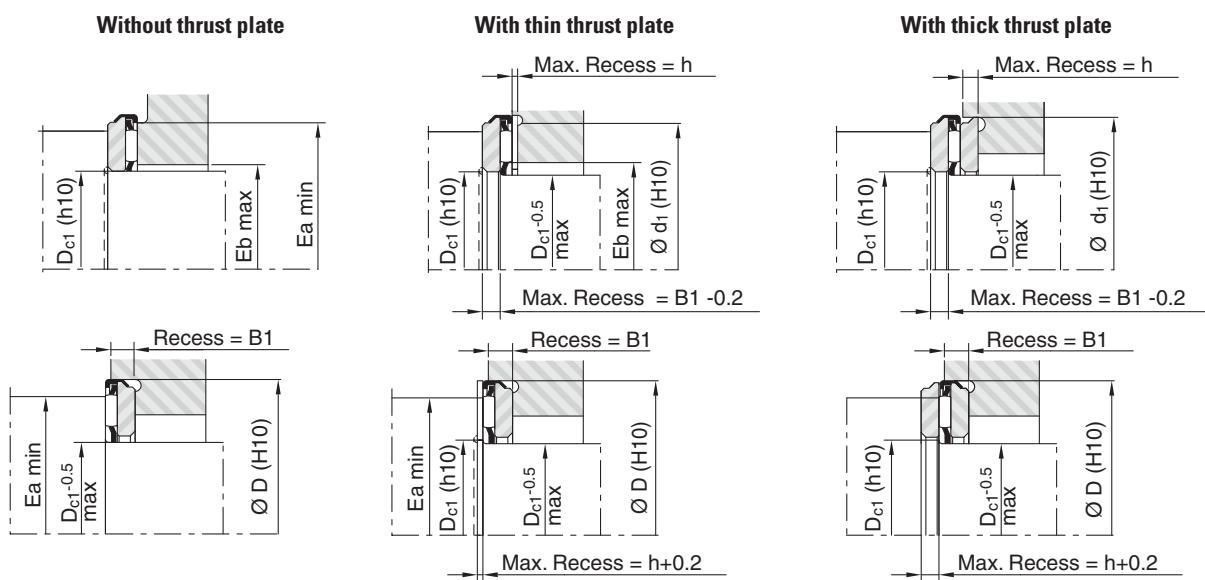

# Mounting arrangements

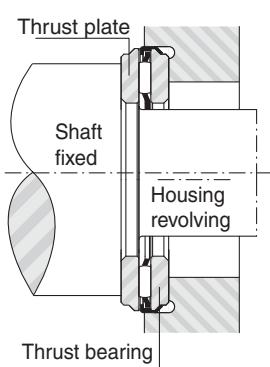

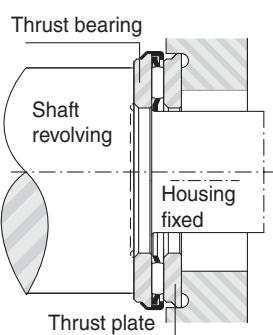

## Needle thrust bearings with thin thrust plate

## Needle thrust bearings with thick plate or light series roller thrust bearings

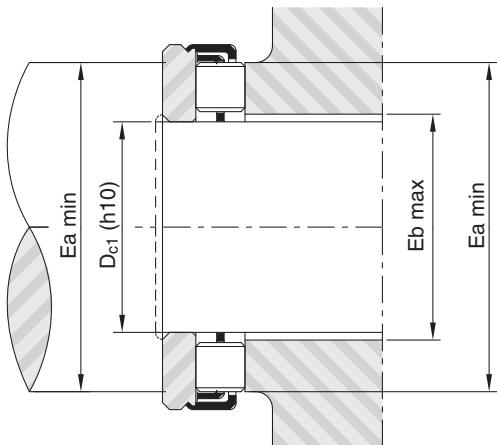

## Mounting for eccentric operation

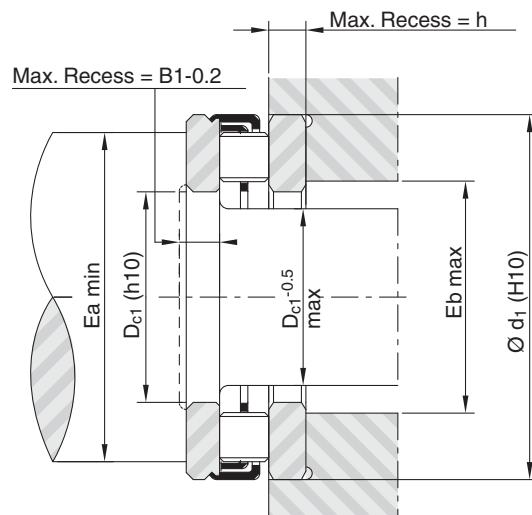

# Mounting arrangements

## Roller thrust bearings AR heavy series

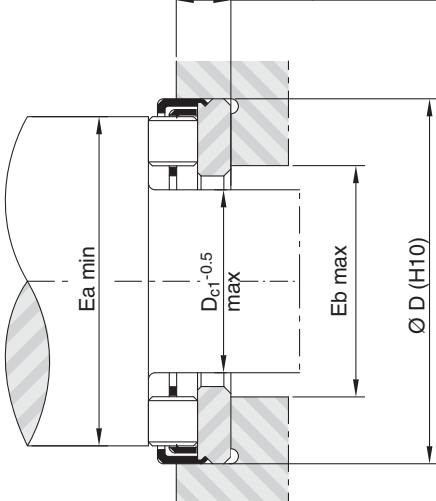

Without thrust plate

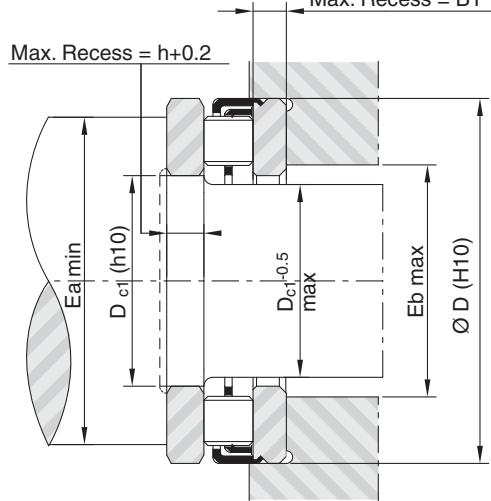

With thick thrust plate

Max. Recess = B1

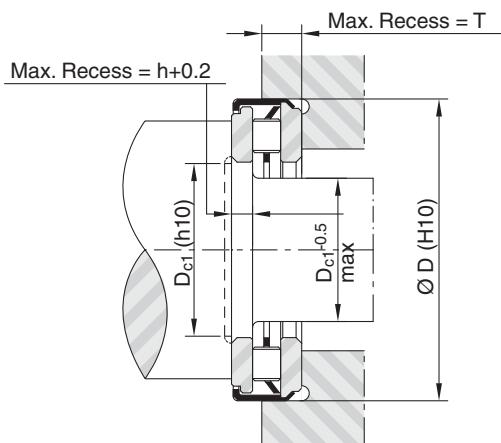

Max. Recess = h+0.2

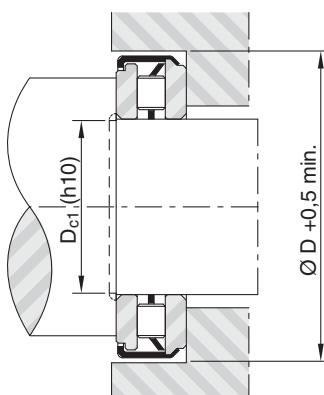

## Needle thrust bearings AXZ or roller thrust bearings ARZ

Mounting for high speed rotation

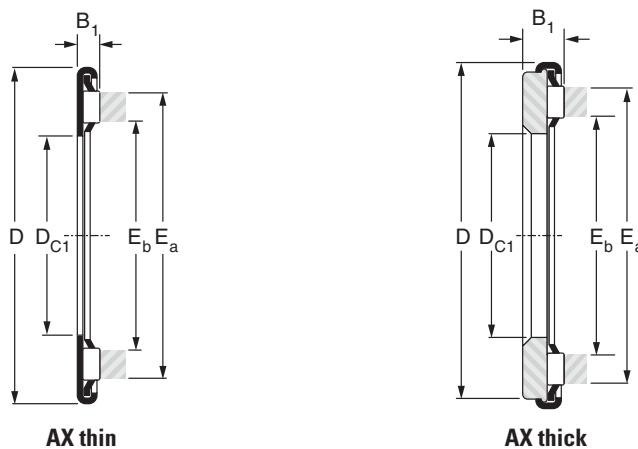

Mounting for slow speed rotation or oscillating motion

# Needle thrust bearings

# COMBINED BEARINGS

---

NADELLA

# Technical features

## Types of combined bearings

Nadella combined needle bearings type **RAX** and derivatives are designed to support simultaneously both a radial and an axial load.

They comprise a needle thrust bearing (or roller thrust bearing) and needle cage retained in a common outer ring.

The technical characteristics of the thrust bearing and the needle cage are set out in the appropriate sections. These bearings form one integral unit permitting easy storage, handling and fitting. Their high radial and axial load capacities and small space requirement enable cost effective solutions to be achieved.

Calculations for combined bearings are carried out taking the axial component and the radial component separately without transforming the axial load into an equivalent radial load.

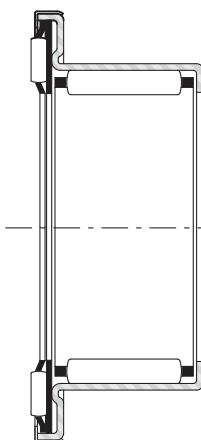

The operation of the thrust bearing and the needle cage independent of one another precludes any interaction harmful to precise axial and radial rotation. Axial expansion of the shaft, for example, will have no effect on the accuracy of the radial component.

The bearings can be used without inner rings or thrust plates, if the shaft journals serving as raceways are of sufficient hardness and possess a suitable surface finish. Hardness of 58-64 HRC will ensure that the full capacity of these bearings is attained.

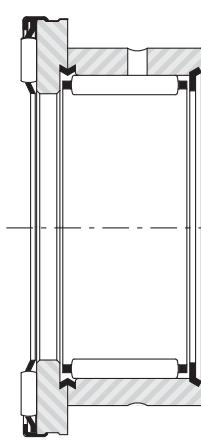

Lower hardness figures will entail a reduction in the static and dynamic capacities (both axial and radial) as shown in the tables of dimensions (see Technical Section).

## Types of combined bearings

### Combined bearings type RAX 700 and RAXF 700

Combined bearings type **RAX 700** possess a one-piece outer ring formed from thin sheet steel accurately controlled and hardened by suitable heat treatment. The shape of this outer ring prevents weakness in the area between the axial component and the radial component, even after the latter has been tightly fitted into a housing.

This type of combined bearing is inexpensive and occupies little space, thus providing a very economical solution. Because they are easy to use and can be fitted rapidly, they are often employed in preference to an arrangement with two separate needle bearings.

Closed-end combined bearings type **RAXF 700** ensure perfect sealing at the end of a shaft and do not require the use of blind housings or end caps.

### Standard combined bearings type RAX 400 and RAX 500

Combined needle bearings type **RAX 400** and **RAX 500** comprise a thrust plate and an outer ring machined separately and joined by a strong metal insert. This arrangement prevents localised stresses and weakness in the area between the two components, thus eliminating the risk of damage during mounting or operation.

Although combined bearings type **RAX 700** should be considered first on grounds of economy, combined bearings with thick outer ring type **RAX 400** or **RAX 500** should be used when operating conditions require higher limit loads or greater rotational accuracy. Moreover, they can be supplied in machine-tool quality type **RAXN**.

### Standard combined bearings type RAXPZ 400 and RAXZ 500

These bearings have an incorporated thrust plate retained by a steel ring set on the thrust plate. They are better protected against the introduction of dust and metal particles and are therefore recommended for spindles of drilling machines.

### Machine-tool quality combined bearings types RAXN 400, RAXN 500, and derivatives

The combined bearings in the **RAXN 400** and **RAXN 500** series are manufactured to the same dimensions as the **RAX 400** and **RAX 500** series in higher precision with respect to out-of-roundness and thickness of the rings and axial run-out of the thrust bearing. These bearings, which are also available with retained thrust plate **RAXNPZ 400** and **RAXNZ 500**, are particularly recommended for use in drilling machine spindles.

## Types of combined bearings

### TOLERANCES OF COMBINED BEARINGS

#### Combined bearings types RAX 700 and RAXF 700

Because types RAX 700 and RAXF 700 have an outer ring formed from thin sheet steel, the radial component of these bearings can only be inspected using a ring-gauge having sufficient thickness to withstand deformation and with a bore ground with great accuracy. The diameters of the ring-gauge and the "GO" and "NO-GO" plug-gauges are identical to those given on page 58 in the inspection table for caged needle bushes type DL having identical inner and outer diameters.

Thickness tolerance of the axial component  $C_1$ :  $\pm 0,1$  mm

#### Standard combined bearings type RAX 400, RAX 500 and derivatives

##### • Radial component

Diameter under the needles  $F_w$ : tolerance F6 (ISO Standard 1206).

Outer diameter D  
Out-of-roundness  
Inner rings JR

Normal tolerance class according to ISO Standard 1206 (see table on page 219).

##### • Axial component

Thickness  $C_1$ :  $+ 0,05 / - 0,06$  mm

Axial run-out max: 0,01 mm

Tolerance	Thin thrust plates		Thick thrust plates mm
	Internal Ø $d \leq 60$ mm	Internal Ø $d > 60$ mm	
Thickness	$h \pm 0,030$ <sup>(1)</sup>	$h \pm 0,050$ <sup>(2)</sup>	$h \pm 0,050$
Max axial run-out	0,020 <sup>(1)</sup>	0,025 <sup>(2)</sup>	0,005

(1) Under minimum load of 150 N - (2) Under minimum load of 250 N

#### Machine-tool quality combined bearings types RAXN 400, RAXN 500 and derivatives

##### • Radial component

Diameter under the needles FW: tolerance F6 (ISO Standard 1206).

Outer diameter D: Normal tolerance class according to

ISO Standard 1206 (see table on page 219).

Out-of-roundness: Precision class 5 according to ISO Standard 492 (DIN 620) (see table on page 219).

Inner rings IM 19000 and IM 20600:

inner diameter d:  $0/-0,010$  mm

outer diameter F:  $0/-0,005$  mm

width B:  $01/-0,130$  mm up to  $d = 40$  mm

$0/-0,160$  mm for  $d > 40$  mm

out-of-roundness: 0,005 mm.

##### • Axial component

Thickness  $C_1$ :  $0/-0,012$  mm

Axial run-out: 0,005 mm

##### • Thrust plates

Thickness h: selected to obtain tolerance h8 on total thickness  $(h + C_1)$

Axial run-out: 0,005 mm.

### RADIAL PLAY

#### Combined bearings types RAX 700, RAXF 700

The fit of a combined bearing with thin outer ring in the housing determines, to a large extent, the dimension under the needles and consequently the radial play during operation.

The recommended shaft and housing tolerances give a radial play whose limits are suitable for most normal applications. To obtain a closer clearance, it is possible to match the shaft diameters with the diameters under the needles of the bearings, after the latter have been fitted into their housings.

The possible differences in the stiffness of housings and the variations of clamping force resulting from the tolerance build up do not permit to establish a range of dimensions under the needles for every application. However, for housings of very thick steel, taking into account the probable restraining force, the variations of the dimensions under the needles after installation will be within the tolerances given below:

$+ 15 / + 50$   $\mu\text{m}$  up to  $F_w = 20$  mm

$+ 20 / + 60$   $\mu\text{m}$  up to  $F_w = 25$  a  $F_w = 40$  mm

$+ 20 / + 65$   $\mu\text{m}$  up to  $F_w = 45$  mm

# Technical features

## Types of combined bearings

The limits of radial play should also take into account the tolerance of the shaft used directly as a raceway or of the outer diameter of the inner ring after it has been fitted on to the shaft.

Where an inner ring is used on a shaft of recommended tolerance k5 (or m5), the minimum play may be slightly lower and the maximum play slightly higher than for the case of an assembly without inner ring on a shaft with tolerance h5.

### Standard combined bearings type RAX 400, 500 and derivatives

#### Bearings without inner ring

The radial play of these bearings when used without inner rings is the difference between the diameter under the needles, which is kept within tolerance F6, and the diameter of the shaft which is machined to the recommended tolerances.

This type of combined bearing without inner ring can be supplied having a diameter under the needles selected in the lower half of tolerance F6 (suffix **TB**) or in the upper half (suffix **TC**) according to the table below.

Nominal dimension  F <sub>w</sub> mm		Tolerance of diameter under the needles		
		Normal F6 μm	TB μm	TC μm
above	to			
da 6	a 10	+13/+22	+13/+18	+ 17/+22
da 10	a 18	+16/+27	+16/+22	+21/+27
da 18	a 30	+20/+33	+20/+27	+26/+33
da 30	a 50	+25/+41	+25/+33	+33/+41
da 50	a 80	+30/+49	+30/+40	+39/+49

#### Bearings with inner ring

The radial play prior to installation of standard combined bearings with inner ring is in conformance with the normal group of ISO Standard 5753. The closely controlled play provided by this standard can be provided on request.

### Machine-tool quality combined bearings types RAXN 400, 500 and derivatives

#### Bearings without inner ring

The radial play prior to installation of machine-tool quality combined bearings results from tolerance F5 on the diameter under the needles, possibly in selection **TB** or **TC**, and tolerances k5 on the diameter of the shaft.

Nominal dimension  F <sub>w</sub> mm	Tolerance of diameter under the needles	
		F5 μm
above	to	
da 6	a 10	+13/+19
da 10	a 18	+16/+24
da 18	a 30	+20/+29
da 30	a 50	+25/+36
da 50	a 80	+30/+43

#### Bearings with inner ring

The radial play prior to installation of machine-tool quality combined bearings results from tolerance F5 on the diameter under the needles and tolerance 0/-0.005 mm on the outer diameter F<sub>w</sub> of inner ring **IM 19000** or **IM 20600**.

## SHAFT AND HOUSING TOLERANCES

Combined bearings	Shaft				Housing	
	Quota F <sub>w</sub> per cuscinetti senza anello interno		Dimension d for bearings with inner ring		Dimension D	
	Rotation	Oscillation	Rotation	Oscillation	Steel or cast- iron	Non-ferrous metal (1) or thin castings in steel
RAX, RAXF 700	h5 (h6)	j5 (j6)	k5 (k6)	m5 (m6)	H6 (H7)	M6 (M7)
RAX, RAXPZ, RAXZ series 400 and 500	h5	j5	k5	m5	K6	M6
RAXN, RAXNPZ RAXNZ series 400 and 500	k5	k5	k5	m5	K6	M6

1) If a housing of non-ferrous metal reaches temperatures considerably higher (or lower) than 20°C, account should be taken of the difference in expansion (or contraction) of the outer race of the bearing and suitable adjustments to the fits should be made.

The cylindrical tolerance defined as the difference in radii of two coaxial cylinders (ISO Standard 1101) should normally be less than a quarter of the manufacturing tolerance.

However, for high precision or high speed applications, it is advisable to restrict this tolerance to the one-eighth of the manufacturing tolerance.

# Technical features

## Types of combined bearings

### SUPPORTING FACES- RACEWAYS

The bearing shoulder must be a flat face at right angles to the housing axis, otherwise axial precision will be affected and the smooth running characteristics of the thrust bearing will be diminished.

Similarly, the shaft shoulder, on which the needles of the thrust bearing rotate or on which the thrust plate is supported, must be flat and square to the axis.

The deviation from true parallelism between the two supporting faces must be no more than:

- 0.3 in 1000, corresponding to an angle of 1 minute, for a combined bearing with thrust plate.
- 0.45 in 1000, corresponding to an angle of 1' 30", for a combined bearing without thrust plate.

In the case of an assembly where neither thrust plate nor inner ring is used, the shaft journal on which the needle rotate must have sufficient hardness, i.e. 58-64 HRC to ensure maximum load capacities are attained.

If the shaft shoulder is used directly as a raceway for the needles of the thrust bearing or, if it supports a thin thrust plate (thickness 0.8 or 1.5 mm), it must be rigid and continuous throughout the area of circulation of the needles bounded by dimensions  $E_b$  and  $E_a$ .

A thick thrust plate can be supported on a smaller shaft shoulder or on one that is discontinuous (as in the case of splines), provided the deflection of the plate does not affect the smooth running or required accuracy of the thrust bearing.

### INSTALLATION

The bearing must be correctly aligned with the housing. It is wise to use a small press fitted with a mandrel having a supporting face square to the axis and covering the whole area bounded by dimensions  $E_b$  and  $E_a$ . This method prevents the thrust component from undergoing shock load which might damage the bearing.

When **RAX** or **RAXF 700** bearings are placed in position during installation care must be taken to ensure that the force exerted by the press does not exceed the axial limit load shown in the table of dimensions.

The fitting of inner rings on shafts manufactured to the recommended tolerances is usually sufficient to render the use of retaining rings unnecessary. However, if it is necessary to employ a ring to support an adjacent pinion, this ring must have an outer diameter slightly smaller than dimension  $F_w$  to enable it to pass smoothly into the bearing when the shaft is introduced.

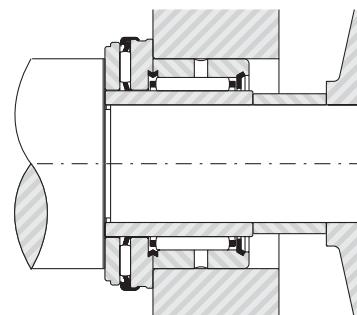

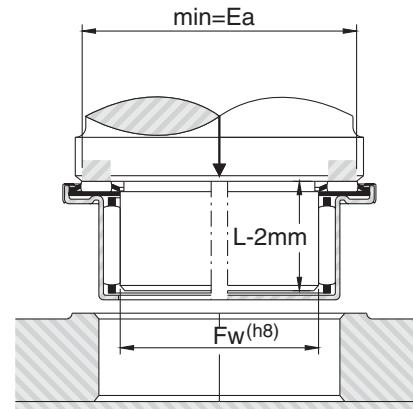

### TYPICAL ARRANGEMENTS USING COMBINED BEARINGS

**RAX** and **RAXF 700**: see page 162.

**RAX 400** (or **500**) and **RAXPZ 400** (or **RAXZ 500**): see page 163.

**RAXN 400** (or **500**) and **RAXNPZ 400** (or **RAXNZ 500**): the typical applications for these machine-tool quality combined bearings used without inner ring and with or without thick thrust plate are identical to those for the corresponding standard combined bearings (see page 163).

The special inner rings (series **19000** or **20600**) designed for machine-tool quality combined bearings are of sufficient width to permit centring of the thrust plate and thus eliminate the need for a shaft shoulder.

# Technical features

## Types of combined bearings

---

### LUBRICATION

When the applied axial loads are relatively high and the application allows the use of oil as the desired method of lubrication, bearing types **RAX 500** should be given consideration. Combined bearings with a dust cap may use oil lubrication, although their design makes them better suited for use with grease lubrication.

Combined bearings are typically shipped protected with a corrosion preventive compound that is not a lubricant. The bearings may be used in oil or grease lubricated applications, without removal of the corrosion-preventive compound. However, it may be advisable to remove the corrosion-preventive compound before packing the bearings (with a suitable grease) to obtain optimum grease performance and to minimize the possibility of confusing grease bearings with bearings containing corrosion preventive.

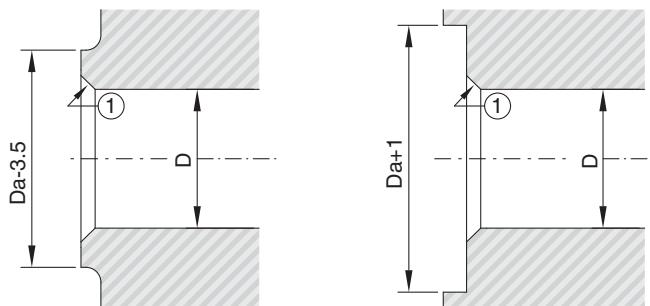

### LOAD RATINGS

Calculations for combined bearings are carried out taking the axial component and the radial component separately without transforming the axial load into an equivalent radial load.

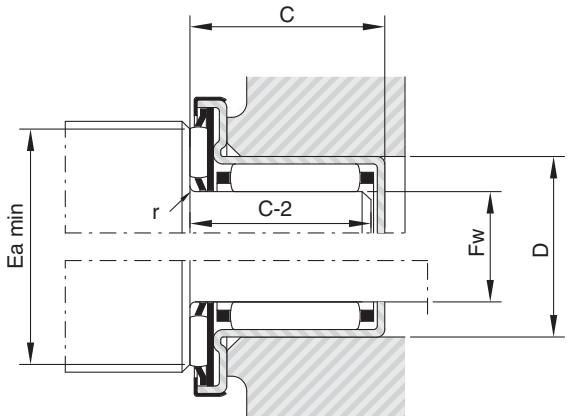

For the meaning of the Load Ratings in the tables of combined bearings **RAX 400**, **RAX 500** and derivatives, see the Technical Section.

Combined bearings type **RAX700** and **RAXF700** has a limitation for the maximum axial permissible load, both axial and radial, because are made in thin outer ring. Limit loads are in the table on page 165.

# PRECISION COMBINED BEARINGS, WITH ADJUSTABLE AXIAL PRELOAD

---

NADELLA

# Technical features

## Precision combined bearings

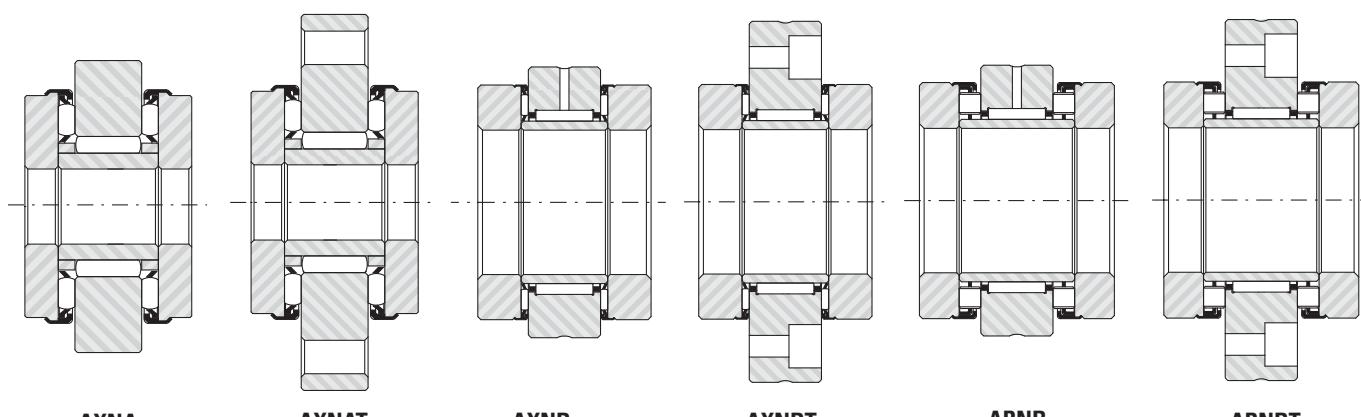

Types **AXNB** and **ARNB** combined bearings and their derivatives consist of a radial needle bearing with cage, in an outer race, with a high radial thickness, each face of which acts as a raceway for a needle or roller thrust bearing. The inner ring, secured laterally between the thrust plates, acts as the inner radial raceway. Combined bearings type **AXNA**, have the same features of previous, but the radial needle bearing is without cage.

These bearings which take up very little space, are particularly recommended for shafts requiring very precise axial positioning, operating under high load, such as leading spindles, ballscrews for numerically-controlled machine tools, drive shafts on control apparatus, etc.

### TYPES OF PRECISION COMBINED BEARINGS

# Technical features

## Precision combined bearings

### SELECTION OF BEARING TYPE

Subject to calculations made for each application, the following general classifications can be made:

**AXNB and AXNBT** bearings for slow speed assemblies with low operating loads; the particularly high axial rigidity of needle thrust bearings, together with the advantages of preloading, ensure a very high axial precision and satisfactory working life.

For example: displacement drive shafts on control apparatus.

**ARNB and ARNBT, series 1 and 2** bearings generally enable preloading to be chosen which suit the precision and working life required of production machine tools.

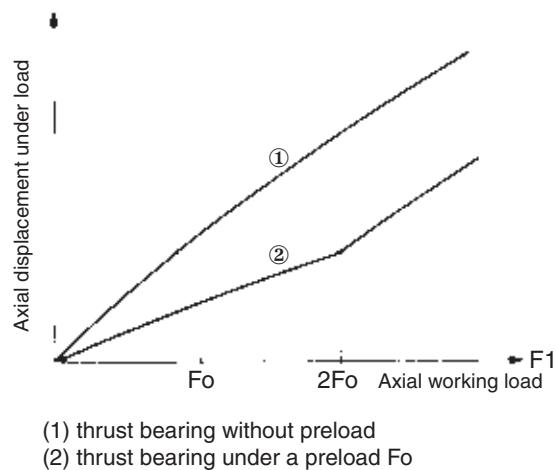

**ARNB series 3** bearings for machine tools, machining units or special equipment requiring very high axial rigidity with high loads and slow speeds.

### PRELOAD

This technique consists in subjecting the thrust bearings to controlled preload during assembly, using an adjusting nut, in order to eliminate play and reduce the axial displacement caused by the operating stress regardless of the direction or the axial load.

In an assembly with an axial preload of  $F_0$ , an operating stress  $F_1$  overloads one of the thrust bearings and frees the other of a load approximately equal to  $F_1/2$ . In an assembly without preload, the loaded thrust bearing must carry the entire stress  $F_1$ .

In a preloaded assembly, the axial rigidity is therefore approximately twice that of an assembly without preload. This result is obtained as long as the operating stress  $F_1$  remains less than about twice the preload stress  $F_0$ . When  $F_1 > 2 F_0$ , one of the thrust bearings is total freed and the other thrust bearing completely carries the load  $F_1$ ; in this case, the axial run-out remains less than it would have been for an assembly without preload (see figure).

(1) thrust bearing without preload  
(2) thrust bearing under a preload  $F_0$

### DETERMINING OF PRELOAD

Preload  $F_0$  should be determined according to the axial precision required under maximum load and the working life required.

The working life of the thrust bearing carrying the greater load depends on the resulting stress applied (i.e.  $F_0 + F_1/2$  when  $F_1 < 2 F_0$  or when  $F_1 > 2 F_0$ ). Since these two cases can both occur on the same machine according to the type of machining carried out, the calculations must take into account the running time ratios under the various loads and speeds.

For more usual assemblies, a preload stress of 5 to 10% of the axial dynamical load carrying capacity of the thrust bearing, is usually suitable.

For certain applications, with slow rotating speeds, for example, the preload stress can be increased to allow for a higher operating load while remaining within the limit of the preload effect, and achieving a satisfactory working life.

### ADJUSTMENT OF PRELOAD

For a given assembly, the shaft torque is defined first, which corresponds to the preload required.

Series adjustments can then be made on each machine by simply checking the torque.

If, as a result of assembly, this is not possible, the nut tightening torque needed to obtain preload is determined separately on the test assemblies. The torque must then be respected for series adjustments. The torque must be measured after starting up the thrust bearing, since it can be up to 50% higher at the beginning of rotation.

# Technical features

## Precision combined bearings

### BEARING TOLERANCES

The outer and inner rings of the combined bearings are manufactured with class 6 tolerances according to ISO Standard 492 (class P6 of standard DIN 620).

The radial play before assembly is kept within the limits of group 2 given for inner and outer paired rings according to ISO Standard R 5753 (class C2 "paired rings" of standard DIN 620).

The axial run-out of the thrust bearing plates is in accordance with tolerance class 4 according to ISO Standard 199 (class P4 of standard DIN 620).

### ASSEMBLY RECOMMENDATIONS

Shaft tolerance: g5 on dimension  $D_i$ .

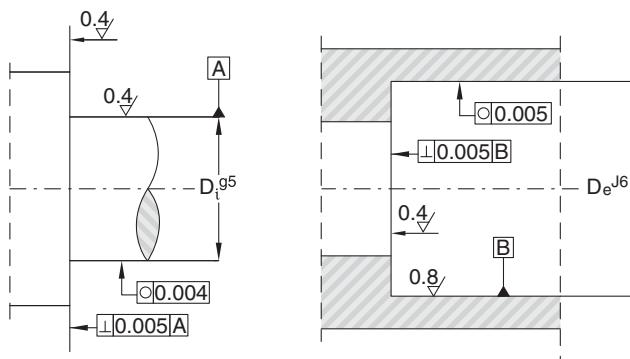

Tolerance of outer ring housing: J6 on dimension  $D_e$ .

The bearing parts of the thrust bearings must be rigid, with plane faces, perpendicular to the rotation axis and of very good surface quality to avoid crushing during use as this decreases the preloading. Their outside diameter must be at least equal to the average diameter of the race, dimension  $D_m$ . The outer ring of the combined bearings should be blocked against a shoulder in order to avoid any axial displacement under load.

In type **AXNA**, **AXNB** and **ARNB** bearings, they are usually blocked by a spacer positioned lengthways during assembly. A flange attached by screws to the frame is located against the spacer (flange and spacer can be in a single piece).

The outer ring of type **AXNBT** and **ARNBT** bearings has three attachment screw holes for direct attachment to the frame.

The surface finish of the outer diameter of the thrust bearing plates (dimension  $D_A$ ) allows the sliding of the seal rings.

### LUBRICATION

The oil used to lubricate the other parts of the assembly is generally suitable for combined bearings whose outer ring has three  $120^\circ$  holes connected by a groove. Grease can generally be used if the rotating speed is in the order of 50% of the maximum speeds given in the dimensional tables. However, special top quality greases enable higher speeds to be reached. By way of information, oils with viscosities of 30 to 150 cSt are recommended.

### EXAMPLES OF CALCULATIONS

#### Choice of bearing

P= stress under which precision is needed

$P < 2 \times$  Preloading

In this field of preloading, the axial rigidity is equal to  $2K$

The interference is  $\frac{1}{2K} P$

Example: If  $P = 7000$  N, ARNB 50 90 will be chosen, since the preloading value is 3800 N and  $2 \times 3.800 = 7.600 > P$

Rigidity in this field  $k = 2 K = 3900 \text{ N} \mu\text{m}^{-1}$

Under  $P$ , the interference will be

$$\frac{1}{3.900} \times 7.000 = 1.79 \mu\text{m}$$

### WORKING LIFE

The hypotheses given in the table below enable the equivalent speed and an equivalent load to be determined according to the maximum load and maximum speed, which enables a rapid calculation of the theoretical working life to be made under average operating conditions.

	1	2	3	4
Loads	$P_{max}$	$0,8 \times P_{max}$	$0,5 \times P_{max}$	$0,2 \times P_{max}$
Speeds	$0,05 V_{max}$	$0,2 V_{max}$	$0,5 V_{max}$	$V_{max}$
Time %	0,15	0,40	0,30	0,15

*Calculation of equivalent speed:*

$$V_{eq} = (0,15 \times 0,05 + 0,40 \times 0,2 + 0,30 \times 0,5 + 0,15) V_{max} = 0,39 \times V_{max}$$

*Calculation of the equivalent load:*

$$P_{eq} \approx \sqrt[3]{P_{max}^p \times V_{max} (0,0075 + 0,08 \times 0,8^p + 0,15 \times 0,5^p + 0,15 \times 0,2^p)} / 0,39 \times V_{max}$$

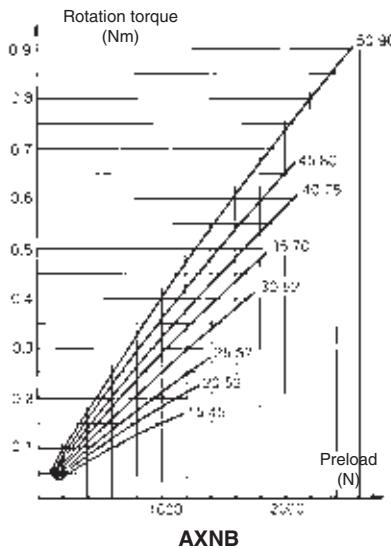

$$P_{eq} \approx 0,575 \times P_{max}$$
$$p = 10/3$$

# SEALING RINGS

---

NADELLA

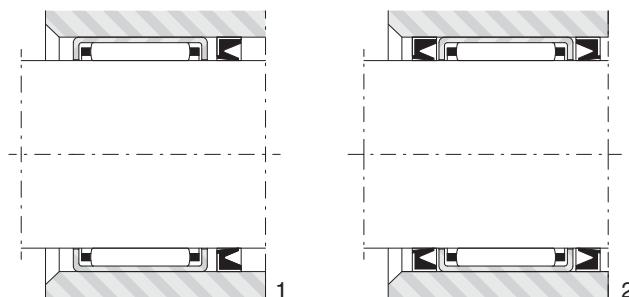

# Technical features

## Sealing rings

Nadella sealing rings type **DH**, made in synthetic rubber and incorporating a metal insert, have the same inner and outer dimensions as Nadella needle bushes and the radial portion of the combined bearings type **RAX 700**. The recommended housing and shaft tolerances for these bearings ensure a tight fit of the sealing ring in the housing bore and the optimum friction between lip and shaft. The simple installation of this seal, requiring no special machining, provides a very economical seal within a minimum space.

In the case of grease lubrication, the seal should be installed with the lip facing away from the bearing (fig. 1) to enable expulsion of old grease when replenishing by means of a pump.

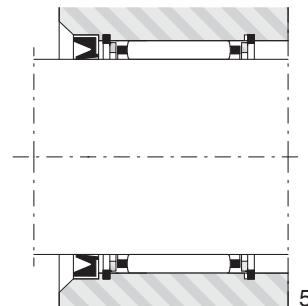

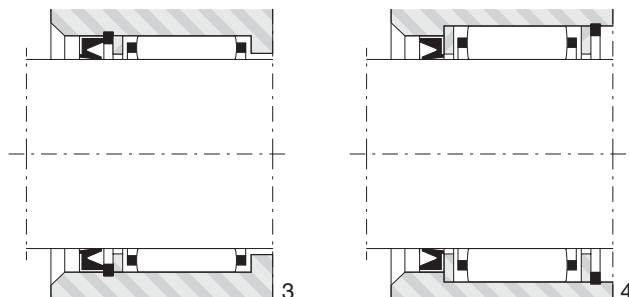

For oil lubrication, installation the opposite way is recommended (fig. 2). If the prevailing conditions are particularly dirty, it may be necessary to protect the seal additionally by means of a labyrinth.

Sealing rings may also be used with needle cages having the same shaft and housing diameters (fig. 3) or with those having larger or smaller housing diameters than that of the seal (fig. 4 and fig. 5).

The hardness and surface finish required for the raceway on the shaft enable these sealing rings to operate at circumferential speeds of 10-12 m/s, providing lubrication is adequate.

Standard type **DH** sealing rings will operate satisfactorily at temperatures from -20°C to + 120°C. For conditions outside this temperature range, please consult Nadella Technical Department.

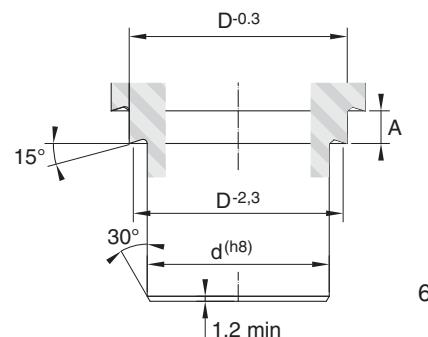

### INSTALLATION

Type **DH** sealing rings should be smeared with grease before mounting- on the outside diameter to facilitate assembly and avoid damage and on the inside to prevent dry operation when starting from rest.

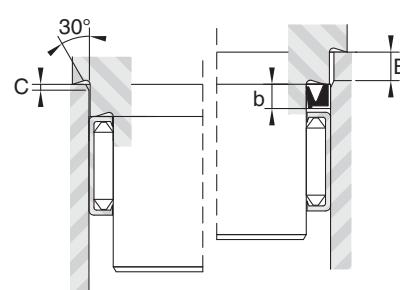

The edge of the housing bore should be chamfered to prevent damage to the seal and to facilitate assembly. A small press should be used for this purpose - such as that used to install needle bushes, in order to guide the sealing ring parallel to the axis of the housing bore.

The needle bush and the sealing ring must be installed separately in two distinct operations. The same mandrel (fig. 6) may be used for both operations: the seal installation being effected by limiting the mandrel stroke with a spacer (fig. 7).

In order to prevent the risk of damage to the seal lip, the shaft end must be chamfered.

# NEEDLE ROLLERS

---

[

NADELLA

# Technical features

## Needle rollers

In certain applications, the limited amount of space available for bearings and the loads to be supported require the use of a full complement of needles independent of any system of retention. The dimensions of the needle, diameter and length, are determined in relation to the load capacity required.

The needles are placed directly between shaft and housing without the use of inner or outer rings. Thus a shaft of maximum diameter is permissible to increase rigidity and load capacity.

In rotating applications where the load capacity requires the use of needles that are long in relation to the shaft diameter, it is preferable to employ two rows of needles of equal length separated by a spacer ring. In such cases, the needles must be selected with diameters in the same tolerance class. This arrangement is particularly recommended for mounting parts such as long idler wheels, especially where they are subjected to rotational torque.

### RACEWAYS

Maximum load capacity is obtained with hardened inner and outer raceways of surface hardness 58-64 HRC. Parts used for the lateral retention of needles at their ends should be of equivalent hardness.

The inner and outer raceways should both be aligned on installation and before operation under load. In the case of parts fitted with a single row of needles, the inner raceway may be ground convex to allow misalignment. A convexity permitting misalignment of 1 in 1000 (or up to 2 in 1000 in cases of instantaneous overloading) does not reduce the calculated load capacity. This convexity, which also depends on the length of the needles, may be produced on a separate inner ring or directly on the shaft journal using a grinding wheel with concave profile obtained by inclining the diamond impregnated cutting wheel. Further technical information is available, consult Nadella Technical Department.

### TYPES AND DIMENSIONS

The standard needle type **BR**, of increased use, has rounded ends. On request, can also be supplied needles with flat ends, type **BP**.

The standard dimensions of the BR type needles are given in the table following (pages 198, 199 and 200). Needles of special dimensions may be manufactured on request.

### CHARACTERISTICS

Nadella standard needles are made in through-hardened bearing steel of hardness 58-65 HRC.

Needles in heat treated corrosion resistant steel (hardness 57-62 HRC) may be produced on request, the preferred diameters being 1.5, 2, 2.5, 3 and 4 mm. The surface finish is 0.2 micron according to Ra system. The profile of a needle is not cylindrical along its whole length as there is a very slight taper towards the ends. Therefore, precise measurement of the diameter can only be carried out in the central area of the needle. Needles having a greater taper at the ends may be supplied on request (suffix ... **DTN**).

### MANUFACTURING TOLERANCES

In general, the diameter of standard needles with rounded ends type **BR** and with flat ends type **BP** is produced to a tolerance up to 10 micron less from the nominal dimension.

However, the maximum variation on any one production lot is 5 µm according to one of the classes of grade G5 in the table below. On request, a variation of 3 µm may be obtained according to the classes of grade G3, and a variation of 2 µm according to the classes of grade G2. Unless specified otherwise, quantities supplied are divided by Nadella into different classes of each grade G2, G3 or G5. However the current supply are generally available in grade G2 according to the classes printed in bold type.

The colour codes shown for class G2 are only used by agreement.

The length of needles type BR and BP is kept within tolerance h13.

### TOLERANCES ON NEEDLE DIAMETER

## Needle rollers

### SHAFT AND HOUSING TOLERANCES

Operating conditions	Shaft Fw	Housing	
		Quota D	Quota B (1)
Rotation on a convex inner raceway	j 5	F 6	H12
Rotation on a cylindrical inner raceway	h 5	F 6	
Oscillatory motion	h 5	G 6	

(1) Nominal dimension B = length of needle Lw +0,2 mm

The cylindrical tolerance, defined as the difference in radii of two coaxial cylinders (ISO Standard 1101), should normally be less than a quarter of the manufacturing tolerance. However, for high precision or high speed applications, it is recommended to restrict this tolerance to one-eighth of the manufacturing tolerance.

### LIMITING SPEED

With effective oil lubrication and good alignment between shaft and housing, limiting speed may reach:

$$n \text{ (min}^{-1}\text{)} = \frac{380\,000}{F_w}$$

(Fw: diameter of inner raceway in mm)

up to a maximum speed of 70 000 mm-1. For grease lubrication, use approximately half these values.

### DYNAMIC AND STATIC CAPACITIES

The dynamic capacity  $C_{Rv}$  in Newton (N), is given by the formula:

$$1) C_{Rv} = K Lu$$

K: variable factor relating to diameter of inner raceway Fw, according to tables on pages 201, 202 and 203.

Lu (mm): effective needle length, as shown in the table of dimensions.

The static capacity  $C_{Or}$  in Newton (N), is given by the formula:

$$2) C_{Or} = 44 \frac{(1 - \emptyset)}{F_w + \emptyset} \emptyset Lu Z$$

$\emptyset$  (mm): diameter of needles

Lu (mm): effective needle length, as shown in the table of dimensions.

Z: number of needles

Fw: diameter of inner raceway in mm.

### NUMBER OF NEEDLES- CIRCUMFERENTIAL PLAY

The number of needles Z is given, as a function of the proposed shaft diameter Fw and the needle diameter  $\emptyset$ , by the formula:

$$3) Z = \frac{\pi (F_w + \emptyset)}{\emptyset}$$

adjusted to the nearest whole number.

To ensure the circumferential play jc, which should normally be between 0.3 and 1 mm, the shaft diameter Fw is corrected with the following formula:

$$4) F_w = \gamma \emptyset + \frac{jc}{\pi}$$

is a variable factor shown in the tables on pages 201, 202 and 203 in respect to the number of needles Z.

Example: needles of diameter d = 2.5 mm on a shaft of diameter Fw = approx. 30 mm.

$$\text{Number of needle } Z = \frac{\pi (30 + 2,5)}{2,5}$$

To ensure circumferential play jc = 0,3 mm the shaft diameter Fw planned is corrected with the formula 4) with  $\gamma = 12,06$  for 41 needles (tables on pages 201, 202 and 203), thus:

$$F_w = 12,06 \times 2,5 + \frac{0,3}{\pi} = 30,25 \text{ mm (adjusted up)}$$

The shaft diameter Fw can therefore be designed at the nominal dimension adjusted up to 30.3 mm to take 41 needles of diameter 2.5 mm, with a circumferential play of approx. 0.3 mm.

Note: Having established the number of needles Z, reference may then be made to the table on pages 201, 202 and 203, giving the corresponding Fw dimensions according to needle diameter and for a circumferential play between 0.3 and 0.6 mm. Thus, for 41 needles of diameter 2.5 mm, diameter Fw is 30.3 mm.

### INSTALLATION OF LOOSE NEEDLE

Because of the large number of shaft diameters possible, depending on the number of needles chosen and their diameter, needles cannot be packed in rings ready for installation.

The needles, which are supplied loose, should therefore be arranged in a ring around the inner or outer raceway, which must be pregreased to ensure their retention during installation of the parts that will retain them.

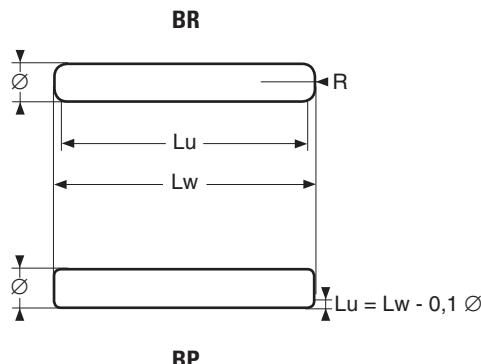

In cases where the shaft has to be introduced blind into a ring of needles, it may be useful to retain the needles in their housing by means of a mounting shaft of the same length as the needles. This can then be withdrawn when the shaft is introduced.

Arrangement of the needles in a ring may be carried out by hand where the number of installations is small. The use of automatic machines with high-speed rotary loading should be considered only for production quantities large enough to ensure that the high cost of investment can be absorbed.

## Inner rings

When it is impractical to meet the shaft raceway design requirements (hardness, surface finish, case depth, etc.) standard inner rings may be used.

Inner rings are made of rolling bearing steel and after hardening, their bores, raceways and end surfaces are ground.

Inner rings may be used to provide inner raceway surfaces for radial needle roller bearings, needle roller bearings and needle bushes with opened and closed end. For a generic bearing with a given internal diameter, there is a choice of inner rings with the same diameter F but of different widths. Normally, the width of the inner ring should never be less than that of the bearing. Alternatively, a cylindrical inner ring wider than the bearing may be used to permit the fitting of a sealing ring, which would locate on the extended portion at one end of the bearing. In this case, if the inner ring has an oil hole, care should be taken to ensure that the hole does not coincide with the ends of the needles

### CONSTRUCTION

Inner rings are available in four basic designs and differ only by the chamfers at the ends of the raceway surfaces, the lubricant access holes and the raceway profile. Inner rings of series **JR** have chamfers to assist in bearing installation but are without lubricating holes.

Inner rings of series **JR.JS1** have bearing installation chamfers and lubricating holes (bore diameters 5 to 50 mm). Inner rings of series **JRZ.JS1** are without installation chamfers, allowing for maximum possible raceway contact.

Inner rings series **BIC** and **BICG** are also represented, to completion of the bearings series **NA**, in addition to the **IM 19000** and **IM 20600** for use with combined bearings RAXN and RAXNPZ.

### Inner rings features

Series	Lubrication hole	Chamfer
<b>JR</b>		X
<b>JR.JS1</b>	X	X
<b>JRZ.JS1</b>	X	

### Nominal diameter of lubrication hole

Series	Internal diameter of the inner ring mm		Nominal diameter of the lubrication hole mm
	>	≤	
<b>JR.JS1</b> <b>JRZ.JS1</b>		20	2
	20	40	2,5
	40	80	3
	80		3,5

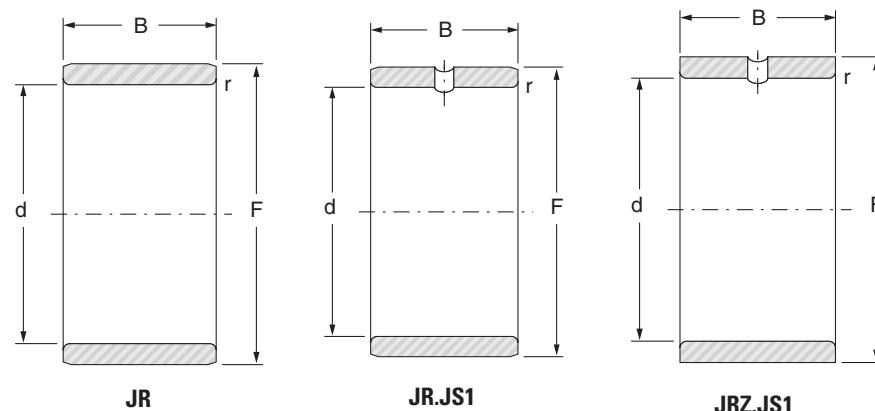

### Construction tolerances of inner rings

Series	Tolerance on external diameter F	Other tolerances
<b>JR</b> With suffix P	h5	According ISO 492
<b>IM 19000 and IM 20600</b>	+0.000 /- 0.005 mm	Contact Technical Service

In the following tables are listed all the inner rings for needle bushes, cages, needle bearings with cages, with full complement and combined bearings that are showed in this catalogue.

# MANUFACTURING TOLERANCES OF BEARING RINGS

## Standard tolerance class P0<sup>(1)</sup>

Inner ring

∅ bore nominal d mm		$\frac{d_m}{2} \mu\text{m}$		Out of round $\mu\text{m}$ max.	Width		Max variation on a ring $\mu\text{m}$		
from	to	max.	min.		tolerance $\mu\text{m}$				
					max.	min.			
2,5	10	0	-8	10	0	-120	15		
10	18	0	-8	10	0	-120	20		
18	30	0	-10	13	0	-120	20		
30	50	0	-12	15	0	-120	20		
50	80	0	-15	20	0	-150	25		
80	120	0	-20	25	0	-200	25		
120	180	0	-25	30	0	-250	30		
180	250	0	-30	40	0	-300	30		
250	315	0	-35	50	0	-350	35		
315	400	0	-40	60	0	-400	40		

Outer ring

∅ external diameter nominal D mm		$\frac{D_m}{2} \mu\text{m}$		Out of round $\mu\text{m}$ max.	Width
from	to	max.	min.		
6	18	0	-8	15	
18	30	0	-9	15	
30	50	0	-11	20	
50	80	0	-13	25	
80	120	0	-15	35	
120	150	0	-18	40	
150	180	0	-25	45	
180	250	0	-30	50	
250	315	0	-35	60	
315	400	0	-40	70	

Tolerance variations on a ring are identical to those of the inner ring for the corresponding bearing

(1) According to ISO 1206 (DIN 620 Class 0).

## Tolerance class P6<sup>(2)</sup>

Inner ring

∅ bore nominal d mm		$\frac{d_m}{2} \mu\text{m}$		Out of round $\mu\text{m}$ max.	Width		Max variation on a ring $\mu\text{m}$		
from	to	max.	min.		tolerance $\mu\text{m}$				
					max.	min.			
2,5	10	0	-7	6	0	-120	15		
10	18	0	-7	7	0	-120	20

180	250	0	-20	25	
250	315	0	-25	30	
315	400	0	-28	35	

Tolerance variations on a ring are identical to those of the inner ring for the corresponding bearing

## Tolerance class P5<sup>(2)</sup>

Inner ring

∅ bore nominal d mm		$\frac{d_m}{2} \mu\text{m}$		Out of round $\mu\text{m}$ max.	Width		Max variation on a ring $\mu\text{m}$		
from	to	max.	min.		tolerance $\mu\text{m}$				
					max.	min.			
2,5	10	0	-5	3,5	0	-40	5		
10	18	0	-5	3,5	0	-80	5		
18	30	0	-6	4	0	-120	5		
30	50	0	-8	5	0	-120	5		
50	80	0	-9	5	0	-150	6		
80	120	0	-10	6	0	-200	7		
120	180	0	-13	8	0	-250	8		
180	250	0	-15	10	0	-300	10		
250	315	0	-18	13	0	-350	13		
315	400	0	-23	15	0	-400	15		

Outer ring

∅ external diameter nominal D mm		$\frac{D_m}{2} \mu\text{m}$		Out of round $\mu\text{m}$ max.	Width
from	to	max.	min.		
6	18	0	-5	5	
18	30	0	-6	6	
30	50	0	-7	7	
50	80	0	-9	8	
80	120	0	-10	10	
120	150	0	-11	11	
150	180	0	-13	13	
180	250	0	-15	15	
250	315	0	-18	18	
315	400	0	-20	20	

Tolerance variations on a ring are identical to those of the inner ring for the corresponding bearing

(2) According to ISO/R 492 (DIN 620). For tolerances of class 4 information on request.

NOTE- For the particular tolerances of a bearing type, please consult the corresponding chapter. In view of the relative thinness of inner and outer rings of needle bearings, their circularity (or ovality) is of little significance, because it is influenced by the shape of the appropriate shafts and housings after installation. This characteristic does not figure in the tables above.
